**A Million Stamps.**—"L. C. R." The story started in England, 10 or more years ago, and has been now and then revived in this country, that if some young lady can collect a million cancelled postage stamps, she can come into the possession of a large fortune. Then the version was, that stamps would be purchased in lots of a million each. There is no foundation for either version. Our correspondent does not believe it, but would like to be able to give a reason for discrediting the idea. That postage stamps which have been used are of no possible use, save as paper stock, and as such, are worth only about 3 cts. per pound, should be sufficient.

**The Adulteration of Butter.**—The occurrence of any more salt in butter than is necessary for its preservation is to be regarded as an adulteration. We do not know if examinations have been made in this country of over-salting for the sake of increasing the weight, but in poor grades of butter in London over 10 per cent of salt was detected, and the same sample contained a large quantity of water, so that the amount of real butter present was but 60 per cent.

**The Apple-Tree Borer.**—Even where the Borer is common but comparatively few understand its history, and we are not surprised that inquiries should come from California where it has heretofore been rare, if not quite unknown. California fruit-growers, who have so long been free from the pests so destructive to their eastern brethren, are, as their State gets older, becoming more and more annoyed by insect pests. The perfect insect of the Apple-tree Borer is one of the long-horned beetles; it is about three-quarters of an inch long, and has a pair of feelers more than half as long as itself; its body is brown, with two broad, nearly white stripes, hence it is called the Two-striped Superda (*Superda bivittata*). The beetle is seldom seen, as it is dormant by day but flies and works at night. The insects begin to appear this month, and next month the female lays her eggs on the bark near the ground. The young grubs soon bore through the bark, and enter the tree, where they live upon the sap wood, just beneath the bark, forming a cell or excavation the size of half a dollar. It lives, eats and grows here for about a year; then, having stronger jaws it in the second summer bores upwards towards the center of the tree, making a hole 3 or 4 inches long, which it then curves outward until its upper end reaches the bark again and, at the beginning of the third winter, it makes a bed and rests, in the next spring becoming a pupa, and soon after changing to a beetle which bores an exactly round hole through the bark at the upper end of its gallery, and comes out into the world to lay eggs to produce more borers. This is the life history of the insect. Any "remedy" must be of a kind to keep the young borer out, or to kill it after it is in. Soap is found to keep off the parent insect. The base of the tree is kept clear of weeds and the lower part of the trunk is

rubbed with soap; the application is repeated during June if washed off by rains. Young orchards are to be examined late in July or early in August. Weeds, trash, and about an inch of soil are removed from around the base of the tree. The bark is carefully examined, if chips are found, or the bark looks dead and dark, cut in to it with a sharp knife and cut the borer out. If the insect has bored upwards, it is to be followed by a wire, a piece of whale-bone, or a twig, and killed.

(Basket Items continued on page 203.)

## Fences and Fencing.

We are greatly obliged to our readers who have responded to the request for reports of their experience in the use of barbed-wire fencing, and though we can present only a very small portion of the communications received, they are highly esteemed, as they supply the information we much desire, in getting at the wants of the country. We solicit still further contributions from those of our readers having experience in the use of such fences,—those not directly or indirectly interested in their manufacture or sale.

A large number of suggestions, plans, etc., for metal posts have come to hand, and are on file for reference, and reply as we can find time. The great rise in iron and steel took away much of the interest in this branch of the subject; but since our last issue there has been a decline of 20 to 30 per cent in the price of iron. The decline is likely to continue from the causes previously referred to, and this subject will, in consequence, have an increasing interest, and new devices and inventions will be in order. In the present issue we make room for extracts from correspondent's letters, taking them almost at random from our letter files.

### Barbed Fences—What Correspondents Say.

R. Noyes, of Coles Co., Ill., writes: "...I have no direct or indirect interest in any fence, except that I want to use the cheapest and best. Six years ago I put up 40 rods of barbed wire fence and each year have added to it, and like it so well that this year I am selling off (good) and burning up (decayed) both rails and board fence, because I think it better and cheaper to build wire fence than to repair the old, although I am making and selling new wooden rails on the place. As to posts, I find that a few good posts answer, with young trees set in the row so that when the posts are gone it leaves your fence an ornament instead of an eye sore. Then it is so cheap. Two wires will turn the worst large stock; three for calves and sheep, and five for hogs. The railroads use nothing else here; and as a man and a boy can put up half a mile in a day, after the posts are set, it saves labor. 'Travelers' do not steal it for kindling or seat boards, nor travel across your land. As to its being 'barbarous,' I have never known an animal really hurt with it, and if they are scratched they will not try it again. The only place I have found it would not do was around small lots where numbers of cattle are kept; they will hook each other through it."

L. B. Goodwin, of Rock Island County, Ill., writes: "...My own fence has only one barbed wire above two boards, and has turned stock thoroughly for two years. When I had a board in place of this wire, we often had the fence broken (mostly by colts rubbing against it), which never has happened since the wire was put on. There is a great deal of barbed wire fence in this neighborhood, and the quantity is increasing. Cattle are 'free commoners' here, and there is a large area of open prairie, where 300 or 400 head of cattle and horses run through the summer, and I have yet to hear of any break in any barbed fence, unless the cattle were stampeded. I know of several instances where horses have been seriously hurt by running against the barbs. One of my neighbors had to sew up 10 gashes on a valuable mare of his which ran against the wire and became frightened, and dashed from side to side of the narrow lane which led to his pasture, some cuts reaching the bone. Another case was where a horse in rolling got entangled in the wire, and was so badly hurt that its owner shot it. I had a pair of colts which were cut slightly,

and they now keep at a respectful distance from any kind of wire. I consider barbed wire as dangerous to stock unaccustomed to it, but as cattle and horses need but one introduction to the stranger, and shun it ever after, we can not afford to dispense with it...."

Warren Stone, of Lyon Co., Kansas, writes us ".... Here on these treeless prairies barbed wire is almost a necessity, and without doubt is a great blessing. The land has lain vacant around Emporia for years, because it was impossible to open a new farm and fence it with boards at the price demanded for lumber here. But now everything is changed; new farms spring up as if by magic. It is only a question of two days to fence a quarter section. We have a post driver here run by horsepower, that has a mallet weighing 200 lbs. A 50-lb. one would make no impression on this prairie-sod. I find that it is impracticable to make a good fence unless the posts are driven and the wire stretched tight. Almost every kind of barbed wire is in use here, and none are too severe; the town cattle will stop for nothing else. We make a very good fence with two wires, that is proof against cattle. The best fences here are two wires with a board between them. I put the board on top so that horses can see it better. But for all purposes I would want no better fence than two wires and a board between. I write this to encourage you in the work of commending wire fences. It is so quickly done; there are no boards to blow off, decay, etc. No other kind of fence is made here since the introduction of barb wire. I think it only a question of time when it will be so everywhere."

Louis Voruz, of Coffey County, Kansas, writes us: ".... I have had a year's experience with one kind of barbed fence, illustrated in the *American Agriculturist*, one with loose twist, four-pointed wire barbs, long and sharp. I had a mare dart through at full gallop, lifting the corner brace post clear off the ground, and sawing a fearful gash across her breast. She however recovered quite quickly. I have about a mile of two-wires fence, with posts two rods apart, and in some places with two stakes stapled between the main stakes. As a rule, an animal which has once been through that fence does not care to repeat the experiment. I am in favor of sharp, straight barbs [standing out perpendicular from the wires, not hooked or inclined in either direction] but not long enough to penetrate the vital part of any living thing. As for injuring people's dress along the public thoroughfares, well, I shall care for that when the majority of said people make it unlawful for stock to range at liberty in the public roads. I am only interested in barbed wire as a buyer for my own use...."

Mr. Voruz gives in detail his simple plan of putting up the barbed wire which is usually sent out from the manufactory wound on a frame or spool. A suitable stick or wooden rod being put through the center of the spool, is laid across the top of the rear end of a wagon box, the projecting cleats preventing it from slipping back. The end being fastened to the first post, the wagon is driven along the line, the wire unwinding from the top of the spool. When the end of the line is reached [or a sufficient quantity is reeled off] this end of the wire is twisted or tied to one of the spokes of the hind wheel next the fence, near the hub. The axle is then lifted to clear the wheel. The team is then unhitched and the wagon tongue fastened to a post or a crow-bar thrust in the ground. Then by turning the wheel by hand the wire winds around the hub, and we have strong lever power, sufficient to stretch the wire very taut through its whole length. It is then only necessary to pass along and staple it fast to the posts. At first the barbs may catch in the grass, and it may be necessary to lift it by hand in some places until a few turns of the wheel brings it up from the ground. The operation is repeated for the other wires. I learned this practice from a neighbor, and hope it is not patented or patentable. [We do not think it is or can be patented.—Ed.]

JAMES R. GILLIS, Louisa County, Iowa, writes: "I am using barbed wire fencing, and find it effi-

cient (if properly constructed) in restraining cattle and horses. I have no sheep, and use board fences to enclose hogs. In Iowa, three barbed wires, or four wires two of which are barbed, make a legal fence. Posts may be two rods apart, but must have a stay lath between, to prevent sagging. The top wire must be not less than 48 inches from the ground, nor more than 56 inches; bottom wire not less than 16 inches, or more than 20 inches. Hogs and sheep are not permitted to run at large.—The common error in building wire fence, is in getting it too high. I think, three wires well strung, not more than 45 inches from the ground to the top wire, will turn any sort of cattle or horses—unless it may be calves that can run under. Stock soon learn to avoid it. Horses may be taught by being led against it a few times. I have used barbed wire fence for some months as a pasture fence for ten horses, and have only had one scratched, and that not seriously. I believe the day is not far distant in Iowa, when we will not be compelled to fence against stock of any sort.—I think I see a tendency on the part of the wire I am using, to rust. Wire put up in November last, has a great many rusty places in it. The paint or tar, or whatever is put on the wire, seems to scale off badly. For putting up long stretches of fence—say 100 rods or more, a steady team is the best appliance for straining the wire, and making it "taut." For short distances, "strainers" of some sort are better. The retail price of wire here, is very little more than before the advance in iron goods."

A. J. Thompson, of Walker County, Texas, writes: ".... Like Mr. Robt. Wood, of Grant Co., Wis., I wish a fence that will keep pigs out, and I propose one, part of wire and part plank; posts of cast iron. Let every alternate post have a mortise 2x12 inches, and the other posts a mortise 1x12 inches. Or, if preferable, let the mortise be 2x6 inches and 1x6 inches. Also have a second 4-inch mortise above the first. The first would receive a plank 1x12 inches, while in the other there would be two planks, each one inch thick and 6 inches wide; this would give about 20 inches from the ground to the top of the plank, sufficiently high to keep out hogs and pigs. The mortise 2x12 inches or 2x6 inches would receive the ends of the plank. Here they would lap, while the center of the plank would rest in the mortise 1x12 inches, or 1x6 inches. If the mortises were made 5 inches above the ground, dirt might be thrown to the plank to prevent anything from passing under. A hole might be cast in the center of the mortise to receive a bolt or ten-penny nail, to keep the plank from slipping, and could be easily removed to renew the plank if it should decay, without interfering with the remainder of the fence. Then place the wire any distance above you may wish, having places cast in the post to receive it. If desirable, mortises might be made in the top to receive a slat 1x4 inches. Stock could see this, and would not run against it...." [At present such cast-iron posts would be too expensive for general use. The same mode of construction could be applied to wooden posts. If the plan here described is not practically useful, it will at least suggest other modes. Ed.]

### Eastern Farmers—Raise More Corn.

We call especial attention to the experiments in Prof. Atwater's article on pages 180-1. Either the unanimous testimony of these trials by intelligent farmers on their farms is false, or corn can be grown at a profit with the right sort of fertilizers. These gentlemen get 50 bushels of shelled corn per acre, which they would otherwise buy at say 60 cts. per bushel, and an amount of stalks which, if rightly fed, are well worth \$10, when ordinary hay is worth \$10 per ton, that is \$40 worth of fodder, at an expense of—including freight—\$9 for fertilizers. And if they feed out the produce, the same rates that they pay for the valuable fertilizing ingredients in commercial fertilizers, will make the well husbanded manure worth the whole cost of the fertilizers. The great point is that the corn, aided by the inexpensive mineral fertilizers, gathers the most costly element, nitrogen, from natural sources. If it can

be established, as these trials imply, that corn can generally do this, that it is, like clover, a "renovating" crop, that fact will be of untold value for our agriculture.—The "bonanza farms" out West will in their turn run out bye and bye. The mineral elements to bring them up can be had at comparatively little cost, but nitrogen in fertilizers is scarce and dear. If corn can gather it for us and give manure for other crops the portent of exhausted prairies is not quite as dismal as our political economists would make it, after all.

### Benefit Yourself and the Public.

Those who omitted to carefully examine the articles on Fertilizers, pages 135-6-7 in the April *American Agriculturist*, should do so at once. There is yet ample time to secure the experimental fertilizers and test them on corn. Every one who does this, will not only gain much information, positive and negative, in regard to his own farm, that can hardly fail to be of great use to him in the future, but every such experiment that is made and reported adds to the amount of general information that will be of great and universal public utility. As a general rule, the fertilizers will more than repay their cost the first year by the increased product realized from their use.

### Science Applied to Farming—LVIII.

#### Fertilizers for Corn.

How to grow corn profitably is an important problem. The main factor is the manure. What are the best and cheapest fertilizers for corn, is a question that deeply interests most farmers in our older States and many of the newer regions.

#### The Feeding Capacity of the Corn Plant.

The first things to be learned are the power which the plant has to gather its supplies of food from natural sources, and the specific effects of different materials upon its growth. Can corn gather its nitrogen from soil and air like clover, or does it, like wheat, require large quantities in fertilizers? Is it especially helped by phosphoric acid like turnips, or is potash more important to aid its growth? Opinions differ widely on these points. There is urgent need of more light upon them. The main question is the nitrogen supply. If, as some prominent agricultural teachers have recommended, farmers must advance from \$10 to \$15 cash in the spring for nitrogen for an acre of corn, run all the risks of soil and season, and wait until winter for the return, the future of corn growing is not bright. But if, on the other hand, we may omit the nitrogen, apply only the inexpensive mineral fertilizers, reduce the yield but little, have the corn gather the nitrogen itself, feed it to stock, enrich the manure, and help bring up the land, that capacity of this grand staple will go far to establish it in the place for which nature seems to have designed it—next to grass, the sheet anchor of farming in the older States. Is Corn an

#### "Exhausting" or a "Renovating" Crop.

In the *American Agriculturist*, for April, 1879, I gave results of some special experiments, to test the question of the nitrogen supply. Similar trials were made last season. The results of the two seasons' work are given in the table, in which the plan of the experiments is also mapped out.

The idea was to compare the effects of mineral fertilizers (superphosphate and potash salt), alone, and the same with nitrogen in different amounts and forms. The nitrogen was supplied as nitric acid in nitrate of soda, as ammonia in sulphate of ammonia, as organic nitrogen in dried blood, and in several forms combined in the "Nitrogen Mixture" and in Peruvian guano. In view of the danger of results being vitiated by irregularities in soil or otherwise, the tests of the effects of nitrogen in varying amounts were duplicated in groups III. and IV. and that of the "Mixed Minerals" in VI. and XVI. Suggesting a careful study of the table for details, I give a brief recapitulation of the **Effects of Nitrogenous Fertilizers upon Corn.**

As regards the effects of nitrogen in different forms, in 1878, the Peruvian guano brought the

largest increase; the "Nitrogen Mixture" (nitrate of soda, sulphate of ammonia, and dried blood in equal parts) next; then followed, in order of valuable effects produced; nitrate of soda, sulphate of ammonia, and last and worst of all, dried blood.

In 1879, with the irregularities in experiment C, and the positively injurious action of the nitrogen in D, the order of efficiency of the ingredients is altered so that in the average, for the two years the sulphate of ammonia comes first, the Peruvian guano second, and the nitrate of soda last. But more trials are necessary to give reliable information as to the action of these materials. The factors of the problem are so multiplex that research will be needed to disentangle and measure them. Estimating a bushel of corn, with its cobs and stalks, to contain 1½ lb. nitrogen, and to be worth

80 cents, the effects of the nitrogenous fertilizers in these "special" experiments and in the general experiments described in the previous articles, may be summarized as follows, remembering that the superphosphate and potash salt, "mixed minerals," supplied the amounts of phosphoric acid and potash in a crop of not far from 55 to 60 bushels, which would also contain about the 72 lbs. of nitrogen.

In the general experiments the mixture of 300 lbs. superphosphate and 200 lbs. muriate of potash brought on the average of fifty-three experiments, about 42 bushels of shelled corn per acre. The special experiments above seem to me a fairer test of what the fertilizers may do, because, while made in

## EFFECT OF NITROGENOUS FERTILIZERS ON CORN AND POTATOES.

EXPERIMENTS FOR STUDYING THE CAPACITY OF THE CROPS TO GET THEIR FOOD FROM NATURAL SOURCES, AND THE EFFECTS OF DIFFERENT FERTILIZERS UPON THEIR GROWTH, WITH SPECIAL REFERENCE TO THE NITROGEN SUPPLY.

Potash and Phosphoric Acid (with Sulphuric Acid and Lime) supplied in proportions contained in a Corn crop of 50 to 60 bushels. Nitrogen is one-third, two-thirds, and full amount contained in same crop. Amounts of fertilizing materials about as are advantageously employed in farm practice.

A 1878. Prof. J. E. Farrington, Orono, Maine. Soil.—Clay loam, heavy, moist, underdrained, worn-out meadow. Weather.—Cold, wet, unfavorable.

B 1878 and 1879. W. L. Bartholomew, Putnam, Conn. Soil.—Hill land, dark loam, compact subsoil, worn-out meadow. Experiment of 1879 on adjoining portions of same fields as experiment of 1878. Weather.—1878, favorable; 1879, cold, unfavorable.

C 1878 and 1879. Chester Sage, Middletown, Conn. Soil.—Heavy loam, hardpan subsoil, worn-out meadow. Weather.—Favorable. Experiment of 1879, on field contiguous to that of experiment of 1878.

D 1878. Col. J. B. Mead, Randolph, Vt. Soil.—Clay loam, compact subsoil. Had oats in 1878. Weather.—Cold, backward, very unfavorable.

\* These low results are doubtless due to irregularities in the soil. Being so palpably abnormal those of plot 16 are substituted in computing averages. † Excluded from subsequent computations for same reason. ‡ Yard manure, 20 two-horse loads per acre. § Stable manure well cured, 15,000 lbs. per acre. || Hog manure. ¶ Hen manure. The "nitrogen mixture" consisted of nitrate of soda, sulphate of ammonia, and dried blood in equal parts.

Or, from a pecuniary standpoint the results show:

	In Trials.	Total Number.	With Nitrogen. Amounts.	Costing.	The Nitro- gen paid for itself in trials.	The Nitro- gen failed to pay for itself in trials.	The average loss in the several tri- als was
1877-8	29	24 lbs.	\$ 5.62½	8	21	\$ 0.90	
	15	48 "	11.00	1	14	4.45	
	6	72 "	16.50	none.	6	8.51	
1879	26	24 lbs.	\$ 5.62½	5	21	\$ 0.90	
	14	48 "	11.00	1	13	9.48	
	6	72 "	16.50	none.	6	16.26	
1878 and 1879	55	24 lbs.	\$ 5.62½	13	42	\$ 0.90	
	29	48 "	11.00	2	27	7.47	
	12	72 "	16.50	none.	12	12.39	

The nitrogen increased the crop enough to pay the cost in thirteen trials out of ninety-six. The pecuniary loss rose and fell with the amount of nitrogen used. With mineral fertilizers alone the crop gathered, as is shown by the above estimates, some 65 lbs. of nitrogen per acre.\*

As regards the effects of the several fertilizing materials, phosphoric acid took the leading place often, potash occasionally, and nitrogen very rarely. In bad seasons, and on some soils in good seasons; neither material had any effect. The most effective ingredient, as might be expected, depended upon the soil and the season.

### Is Corn in Its Relations to Nitrogen, more Closely Allied to the Cereals, or to the Legumes: To the Grains or to Clover?

One thing detracts from the decisiveness of the experiments. Most of the trials were on old grass land which contained large quantities of roots on which the corn doubtless fed. How well it could provide itself with nitrogen from nitrogen compounds in the soil and from air without the roots to feed upon is not settled. But the trials that have been repeated on the same plots imply that the corn did not depend greatly upon the roots of previous crops for its nitrogen.

\* I may add that Mr. J. W. Sanborn, Farm Superintendent of the N. H. Agricultural College, has conducted experiments for two years on a similar plan, and, with a smaller quantity of the superphosphate and potash salt, got 37 bushels in 1878, and in 1879, on the same plot, 67½ bushels. By the addition of nitrogen, the yield in 1878 was increased, but diminished in 1879, as in the experiment of Col. Mead, of Vermont (D, of the table).

The experiments are numerous and decisive enough to warrant the inference that, as corn is commonly grown, nitrogenous fertilizers in any considerable quantity would be rarely profitable. They imply that corn has somehow or other the power to gather a great deal of nitrogen from soil or air, or both, and that in this respect it comes closer to the legumes than the cereals, that it is more like clover than wheat—that, in short, corn may be classed with the "renovating" crops.

### A Question for Further Investigation.

Corn is botanically allied to wheat. The cereals, generally, demand large quantities of available nitrogen. But in all these experiments corn makes little response to nitrogen, or is positively damaged by it, and does well with the mineral fertilizers. Why, how, or to what extent the implied conclusions are true I do not presume to say. The subject evidently demands much more thorough study.

### Practical Application.

According to the tables in last December's *American Agriculturist*, the several valuations of digestible ingredients that would make the feeding value of a ton of fair hay \$11.00, and of a bushel of shelled corn 60 cents, would bring a ton of well cured corn-stalks at \$8.00. Reckoning the stalks at only \$6.00 per ton and 1½ ton to the 50 bushels of shelled corn which came with the mixture of 300 lbs. superphosphate and 150 lbs. muriate of potash, the value of the crop for fodder would be \$40.50.

Supposing the crop to be fed on the farm, two-thirds of its nitrogen, phosphoric acid and potash, reckoned at prices ordinarily paid for them in equally valuable forms in commercial fertilizers, would be worth \$8.50, the cost of the fertilizer. The fertilized crop probably leaves the land in about as good condition as it was before; the manure, well husbanded, more than pays for the fertilizer, and there remains over \$40.00 worth of fodder in return for labor and rent of an acre of land. It strikes me that farming of this kind is profitable and practical.

### A Word to Our Experimenters.

I wish to warmly second the proposals of the Editors of the *American Agriculturist* for experiments with fertilizers the coming season, and hope that as many as possible may join in the trials, and that those who made them last year will repeat them the coming season.

W. O. ATWATER.

all sorts of weather and on worn-out soils, they were all on soils and in latitudes fit for corn, as many of the general experiments were not. In these, the mixture of 300 lbs. superphosphate and 150 lbs. of potash salt, which can be bought for \$8.25, brought on the average 50½ bushels of shelled corn per acre.

The experiments of the two seasons bear unanimous testimony to two things: The corn was helped but little by nitrogen in the fertilizers; and it gathered a good deal from natural sources. The increase of crop and of nitrogen in the crop will appear more clearly if we look at it another way.

**A Cottage for the Country Costing \$1,800.**

BY S. B. REED, ARCHITECT.

These designs are for a roomy and home-like country dwelling with ample accommodations for a family of average size, and containing some of the most essential of modern improvements.... **Exterior** (fig. 1).—The ground measurements are 36 by 41 feet—giving a desirable breadth of base each way. The outlines are irregular, and broken

Fig. 1.—FRONT ELEVATION OF COTTAGE.

with sharp, well defined angles, which impart an appropriate rustic appearance, that will be picturesque on a level, monotonous prairie, while it would harmonize with rugged surroundings. There are two pleasant verandas—one in front, and one in the rear of the Living-room. In some localities it would be desirable to extend the front and rear windows of the living-room to the floor, making both verandas directly accessible.... **Cellar** (fig. 2).—Height 6½ feet, and of the same size as the main house, giving abundant room for ordinary purposes. If desired, a solid partition may be made in line with the girder (shown by dotted lines), thoroughly dividing the space at little cost;—and giving a

Fig. 2.—PLAN OF THE CELLAR.

“warm cellar” on one side, and “cold” one on the other. There are six small windows, admitting light from three directions, an outside entrance at the rear is inclosed with hatchway doors. Should more cellar space be required, it may be extended under the kitchen while building, at an additional cost of twenty dollars.... **First Story** (fig. 3).

—Height of ceilings 9½ feet. The front entrance leads from the veranda to the main hall, which is centrally located, and communicates directly with the four principal rooms on this floor, and contains the main stairs to the second story. Each of the rooms is conveniently situated, and has the necessary windows to admit plenty of light and air. The dining-room and kitchen have each outlooks in three directions, and are arranged to communicate with each other through the pantry, which is thoroughly shelved, and has a narrow window. A door opens from this pantry directly to the cellar stairs, which are under the main stairs. Many prefer such connection between the pantry and cellar for convenience. A large proportion of the stores required for the table, come directly from the shelves and safes in the cellar, and by this plan many steps are saved. The kitchen is conveniently arranged. An outside door opens from the rear veranda. A good sized pantry, C, an open fire place, a pump, sink, and a closet under the sink, are provided. The fireplace is suited to the use of a range with water-backs, placing the boiler at the side of the chimney if desired.... **Second Story** (fig. 4).—Height in the main house 5 feet at the plates, and following the rafter to the full height

of 8 feet; height in the wing 2 feet at the plates—to 6½ feet in the center. The roofs are unusually steep, so that a person of ordinary height will be able to stand erect within six inches of the sides of the principal rooms at their lowest point, making them as useable for chambers, as if with full height or level ceilings. Each of the principal chambers have closets adjoining the chimneys. One chamber suitable for a servant's room, a bath room, and a store room, are placed over the kitchen. The bath room is furnished with a seat closet and bath tub. An opening with register is placed in the floor at R, admitting warm air from the kitchen ceiling....

**Construction.**—The foundations are of brick, where stones are not plentiful and cheaper. The walls show 2 feet above the earth grades. The Chimneys are also of brick, having continuous flues from each fire-place and the cellar, and have tops laid in cement mortar. Timber of sawed spruce; siding of pine, “Novelty” pattern. Roof of pine shingles, on spruce lath. Flooring, outside of narrow pine, inside of wide spruce. Plastering three coats and hard finished. The Windows have sash with four lights in each. If desirable the windows facing the verandas may extend to the floor. The sash for these should be similar in every respect to the others. A panel is fitted under the sash and hung to swing like a door. This will be found a very simple and satisfactory method of extending windows to the floor. No special, and, therefore, expensive sizes are required, but all may be of uniform and stock dimensions. When completed they match other windows in the same apartment, in appearance and in their usual operation, and may be readily passed by raising the lower sash and swinging back the panel. Five marble shelves with stucco trusses, are set in the principal rooms. Plumbing is similar to that described in the *March American Agriculturist*, with the addition of bath room fixtures. The veranda roofs are shingled. All valleys and gutters are of tin. The method of constructing these gutters is shown on page 173, May, 1875, *American Agriculturist*. Painting inside and out of pure lead and linseed oil.... **Estimate.**—Cost of materials and labor is given with the same figures as that in previous months:

**Exhaustion of the Soil.**—A Subscriber in Indiana writes: “A great many farmers in this section, believe that wheat will never exhaust the soil. They claim that they have kept wheat on the same ground for a series of consecutive years, with good results, etc.” The mineral portions of the plant—the potash, phosphoric acid, magnesia, lime, iron, etc.,—must come from the soil, and are taken up in a state of solution by the roots of the plants. These substances are deposited in the plant, and if they are removed from the soil in the form of grain,

Fig. 4.—PLAN OF THE SECOND STORY.

straw, or any other crop, the soil loses just so much of these essential ingredients of plant growth. If there is a continual outgo, and no income in the form of manure, or other fertilizer, it is only a matter of time for the richest soil to become poor in plant food, and it will fail to produce remunerative crops, and the soil is then said to be exhausted, or “run down.” There is no reason why the wheat plant should not tend to exhaust any kind of soil.

### The Famous Jersey Cow "Alphea."

The credit and fame of breeding such a cow as "Alphea" the daughter of "Saturn" and "Rhea" ought, we think, to be about as great a satisfaction as to be the producer of that miracle of mechanical art and automatic performance; the Hoe Press.

There are few of our readers, who do not know something of "Alphea"; all such, and others not

ful feature, as shown, indicates full capacity for effective work. She was, as might be supposed, a good feeder; no cow can give milk in such quantity and of such quality as hers without an abundance of food and ability to digest it. "Alphea's" milk and butter record depend entirely upon the testimony of Mr. Geo. W. Harris, who was Superintendent of "Brightside"—Col. Hoe's beautiful residence and farm in Morrisania, now

ter was in no instance less than 3 lbs. This would make the yield 4 lbs. a day while she was giving 24 quarts of milk, which, it requires very little calculation to see, is the remarkable total of 28 lbs. a week.

This has never been claimed—the writer of the articles entitled "Among the Farmers" claimed 22 to 24 lbs. per week, "Hark Comstock" claims 25, but we see no reason why the old cow should not have the full meed of her wonderful record, and be

THE MOTHER OF THE ALPHEA FAMILY OF JERSEYS, "ALPHEA" (171).

less, will be interested in the beautiful portrait, from an instantaneous photograph by Schreiber & Sons, of Philadelphia, which we present herewith.

"Alphea" was a beauty, regarded either from a purely æsthetical standpoint, or from the more practical one of "handsome is that handsome does." Of still more importance her qualities did not die with her, when in her full prime she sickened and died of an inflammatory disease in no way connected with her extraordinary milk and butter production, but they live in her descendants to whom she imparted to a greater or less degree both vigor of constitution, and a butter-yielding ability.

"Alphea" herself came from the crossing of two animals of similar characteristics, imported by Col. R. M. Hoe, of New York and Morrisania, N. Y., and inherited a most excellent constitution. She was of a color called solid dark fawn with black points—that is, brown of various shades running into nearly black and shading off into light French gray, changing also somewhat with the season of the year. As may be seen from the engraving, she had the characteristic wedge-form of the best milch-cows, light in front and heavy, inclining almost to coarseness, behind. Her head was delicate and the horns light, and incurved, yet the muzzle was broad, and this important and use-

within the limits of the City of New York. During the greater part of the season through which the tests extended, Col. Hoe was in Europe, hence the matter was left entirely to Mr. Harris. This was in the year 1868, and in a recent article in the "Country Gentleman," by "Hark Comstock," it is stated that Mr. Harris' reasons for not himself publishing the extraordinary record were that the tests were not made in the usual way, and special explanations would need to be made. His explanation is entirely satisfactory to any one who knows either Mr. Harris or Col. Hoe, who gives Mr. H. his confidence, and leave no doubt on the record.

A statement of the yield was made in the October number of last year, page 381, which, we believe, was the first publication of the facts. Doubt was cast upon the statement in certain quarters, but the most rigid scrutiny, as made by the author of the article in the "Country Gentleman," confirms the statement then made. There seems to be no doubt that "Alphea" during this season yielded from 24 quarts of milk a day when fresh, down to 20 and 18 and less, while these tests were being made. The churn in which the milk was churned, and the whole milk was used every time, held conveniently 18 quarts, and this amount well averaged was churned every time, and the yield of but-

set down as leading the World of dairy cows, with the astonishing record of 28 lbs. of butter per week.

"Alphea" bred to her own brother, "Jupiter 93," produced a line of fine looking, good-constituted cows and bulls which have been rather closely bred together, with now and then a promising out-cross.

### Among the Farmers.—No. 52.

BY ONE OF THEM.

#### "More Nice than Wise."

Can one be "more nice than wise" about milk? There is a satisfaction in being very particular, and fastidiously nice and neat in personal habits, about what one eats and drinks, and all that, but we can carry the thing too far for our own comfort, and for those around us. One of my neighbors will buy no article of food a second time, at a store where the salesman wets the finger in the mouth to pick up the wrapping paper more easily. He is shocked at the idea of carrying off another human being's saliva; and yet my friend will sit in a crowded rail-car or room, and breathe the vital air second-handed, by the hour.—While it is well not to be too nice about some things, in the matter of milk, I think there is the highest wisdom in extreme niceness.

### Earthen, or Tin, Milk Vessels.

I fancy I can tell the difference in the taste of milk set or kept in earthen or glass, and that set or kept in tin; nay, I do not think it is a fancy or a piece of "fast-idiocy"—as a jocose friend would say, as he once remarked he was no "fast idiot."

I found in use on Col. E. S. Sanford's farm, last summer, some curious milk vessels. They were wide-mouthed jars, or ewers, of common earthen-ware, glazed inside, unglazed outside, with one or two handles, according to size. I find that they are a good deal in use among Germans in and about New York and the group of surrounding cities and villages. The sizes are two, three, four, and six quarts—a three-quart jug is shown in figure 1, and a larger one in figure 2.

Fig. 1.—A GERMAN CROCK.

They have covers which fit into a rim like the lid of a butter crock. They are filled with milk and set into water in pans or tubs—or other crocks—and the water is renewed as often as may be convenient. The outside is so porous that the water, if it once

wets the surface, is continually drawn up by capillary attraction. It of course evaporates all the time, thus notably cooling the milk. I procured some of these German milk crocks, and found them excellent where one has but a few quarts of milk—but we were disappointed in the degree of coolness produced. I am satisfied that for some reason, milk will keep sweet much longer in earthen than in tin vessels. When travelling at the West—I mean what we used to call the West, properly the Interior—and at the South, I have noticed coarse earthen pans with flat rings, quite thick and heavy, covered with a dark clay glaze. Upon inquiry

Fig. 2.—CROCK IMPROVED.

I was surprised to find that they were milk-pans, in fact—except among people of New England or Eastern origin—the common milk-pans of the country. I sketch one of them (fig. 3) from memory, and a stack of them in figure 4, to show how solidly they pack. They are, I should say, 5 inches deep and hold, when filled to the proper height, from four to six quarts.

Very neat milk pans, made of yellow or white ware, are sometimes used and are by far the best

round shallow pans. They are called by the trade "nappies," and are round or oval, shown in figures 5 and 6. The convenient sizes hold 4 to 6 quarts; the 8-

quart ones are heavy to handle. The round ones with a lip were formerly made extensively for the southern trade, but less so now. Square dishes of the same ware are called "puddings;" they are rectangular with somewhat rounded corners, and in common use as pudding dishes, but are admirable milk-pans when small quantities of milk only are kept. After the milk is two days old, in ordinary weather, the cream may be loosened from the sides of the pan and slipped off from the skim-milk by a dex-

texous movement, with greater ease than from pans of any other form. See the process in figure 7.

It must not be overlooked that there is little lost room on shelves or tables where these pans are placed. Cream is often "slipped" from round pans of both tin and earthen-ware, but a good deal of milk is liable to go with it. The influences of the weather on milk are well known; we all think thunder and lightning sour milk, and the warmth and cold, as well as the moisture and dryness of the atmosphere produce notable effects. These effects are increased by metal, and diminished by glass, porcelain, and earthen-containing vessels.

### The Peculiar Flavor Caused by Tin.

We are so accustomed to use milk which has been drawn, transported, or set in tin, that most of us are quite unaware that a foreign flavor is almost uniformly imparted. Perfectly bright, new tin, probably imparts no perceptible flavor, but that which has been somewhat worn, scratched, or scoured, flavors the milk at once. It is fair to conclude, then, that it is the iron and not the tin which gives the flavor; for where the iron is laid bare, from any cause, it is this and not the tin which is primarily acted upon by the acids of the milk. The least action causes the formation and disengagement of hydrogen, which, either by itself, or in the form of some of its many compounds, of which I know

Fig. 4.—STACK OF PANS.

Fig. 5.—ROUND NAPPY.

Fig. 6. "SQUARE" NAPPY.

little, I believe is absorbed by the milk and imparts a peculiar flavor. This taste is more perceptible in skimmed milk than in the cream—if it be at all observable in cream and butter.—I do not at present know of any reason why the so-called

### Granite Ware,

if the glaze which covers the iron basis does not crack and does not contain lead in such quantity as to render the glaze partially soluble, should not form an excellent substitute for both tin and earthen-ware for setting milk, and other milk vessels.

### Bitter Butter.

Few persons will be troubled with bitter butter after this article is before the readers of the *American*

Fig. 7.—SLIPPING THE CREAM.

*can Agriculturist*, because grass feed, fresh cows, and the season of the year prevents its occurrence. My attention has, however, been repeatedly directed to the subject the past winter, and I am certainly inclined to favor the view that the bitterness arises from the milk which separates from the cream after skimming, and which is usually churned with it. It has been repeatedly suggested that this milk

or sour whey should by all means be drawn off before churning; but I do not recollect that the

### Washing of Cream

has ever been recommended. I have proved that it is easily done in this way: one may draw off the milk from the stone cream-crock—like the one shown in figure 7—or from any other cream vessel; add an equal quantity (or say, a portion equal to one-fifth of the cream), of skimmed milk, and stir the whole together. This may stand awhile, and be drawn off before churning, and more may be added if one wishes to churn with a portion of milk, or the milk of the second washing may be drawn off and the cream then cleansed, washed and rinsed, and churned by itself.

This washing of cream is a matter which I have experimented with very little, and know little about. So far as I know it is an original idea, and I would be glad to have older and wiser dairymen—and I am not properly a dairymen—experiment with it. That cream may be washed with sweet milk, sour milk, whey, buttermilk, water, or brine, is certain. What the effect of washing with these fluids will be upon the butter has yet to be proved, so far as I am aware. I certainly should expect the best results from washing with sweet skimmed milk, water, or brine. The use of brine is strongly favored by a very sensible Vermont dairymen, with whom I was recently conversing. He is a great advocate of brining butter, and uses three strong brines in preparing his butter, which, by the way, he finds to add the equivalent of a quarter of an ounce of salt to the pound. It may be that he regards the brine as applied to washing cream with too great favor. Nevertheless brine is the butter-maker's sheet anchor in modern butter-making, and I see no reason why it should not answer—and answer well—for washing cream. Thus far I have only experimented in the use of skimmed milk and water.

### Something About Milk.

The following remarks, abstracted from a foreign scientific journal, are applicable to this meridian, and may be useful to producers and country users of milk, as well as to consumers who live in cities.

First of all, it should be understood that a hard service is required of milk. Nearly the whole of the vast demand made upon it by civilization is outside of its natural functions, and is—so to say—rather unfair treatment of a very sensitive nature, for Nature never designed milk for exposure to the air, or for much variation of temperature. It was intended to be taken directly from the fountain. It is what chemists call a *transition compound*, therefore, changeable and transitory, and requiring delicate handling. It comes directly from the blood, which is very similar, it naturally passes, without delay, exposure, or appreciable change of temperature, from the body of the parent to that of the offspring, there to be immediately converted to blood again, and so used in growth and sustenance. How can we expect that such an exquisitely delicate compound will not occasionally resent outrageous changes from heat to cold, and cold to heat, and the ruthless joltings of transportation and contact with air of every degree of impurity?

To refer only to the latter, which is probably least understood. Almost everything is capable both of giving out and of imbibing *effluvia*, or vaporous compounds, which are often quite beyond the reach of chemical estimation. Probably but few persons outside of scientific circles are aware that it would be next to impossible to devise a compound liquid more susceptible to effluvial influences than fresh milk. It possesses a slight and agreeable effluvia of its own; and also a wonderful aptitude for receiving and retaining that of every sort of volatile matter approaching it. Oily matters promptly take up odoriferous principles of every kind; the microscopic globules of the rising cream, in their state of minute subdivision present a large surface, absorbing with extreme avidity. When the milkman leaves the daily supply of, we will suppose, pure milk, this is what is likely to happen to it in England, according to our narrator:

"It is poured at once into a clean earthenware jug." [The Englishman means *pitcher*, but a fashion

only about fifty years old has substituted the word jug for pitcher so largely, that few educated Englishmen know, as we do, what the two words denote in our common English language]. "This is stood [he means set] say on a stone shelf in the larder, to keep it cool and free from taint. Its companions there are a joint of cold meat, in its gravy, a few unfinished tarts, a large bowl of scrap bread (with incipient fungoid growth), a couple of dozen of eggs, not all fresh; underneath, the cheese; overhead, a jar of onions in pickle; in the near distance, a few head of game in an advanced state of

Fig. 1.—THE CHURN IN PLACE.

—well, 'keeping,' and last, not least, a closed window. Now, what is the action hereupon? A thousand to one the temperature of the milk when received is different from that of the air, whether higher or lower. As soon as it comes to rest the surface next the air becomes warmed or cooled, as the case may be, and by giving place to other portions, sets up a series of gentle currents, by means of which every part of the fluid is successively brought into contact with the air, and its countless crowds of butter-corpuscles, containing fatty matter in a high state of subdivision, are enabled to expose the greatest possible extent of surface. Now, it is scarcely the fault of that milk if, in ten hours' time, it has failed to lay by at least a trace of every shade of effluvia which has had a chance of circulating near it. And yet, when the pardonable nastiness of that milk is commented upon at breakfast, there will not be found wanting some one to exclaim: 'What can those people feed their cows on?'

### To Fasten Down a Churn.

Mr. E. A. Cooley, Sonoma Co., California, sends sketches of a handy device of a pattern in frequent use, for fastening a churn to its place upon the

Fig. 2.—A SHELF FOR A CHURN.

table while in operation. "To make it, two cleats, beveled on the under side, are nailed to a board in such a manner, that when the churn is slipped in place, its feet will closely fit under the cleats, and be held by them." The arrangement of the cleats of course will depend upon the size and kind of the churn. In Mr. C.'s case, it is as shown in figure 1. "For convenience, we have the arrangement hinged to the wall, and supported by a movable standard,"

which is shown in figure 2. The table when not in use, hangs against the wall, and is entirely out of the way—the movable standard, which reaches from the floor to the shelf, may be kept from going astray by providing it with a cord, which keeps it always at hand when the table is desired for use.

### Butter Making Without Churning.

Probably most of our readers have heard of the method of making butter by placing cream in a bag of some close fabric, and hurrying it in the ground. When the bag has been hurried for 24 hours, it is taken up, and the contents are found to be converted into butter, which only needs washing to be ready for use. In this case the bag is subjected to the pressure caused by the weight of the earth upon it, which forces out the liquid portions of the cream, that are at once absorbed by the surrounding earth. Acting upon the principle that simple pressure within a close fabric is sufficient to separate the butter globules from the liquid portions of the cream, a Prussian lady, Mathilde Ziemann, of Quedlinbourg, has invented a press for the purpose, and also to remove whey from the curd, in the making of cheese. As this method of butter-making is attracting much attention abroad, we give our readers an engraving of the press, from the *Journal d'Agriculture Pratique*, with an abstract of the account there given. As the making of cheese by pressure presents nothing new, save the pressing the curd in thin layers in bags, we omit that use of the press for the present, and describe the method with butter. The press consists of a base, sufficiently inclined for liquids to run off, from which arise four iron rods supporting the top. Press-boards, or shelves, are provided with notches at the corners to receive the iron rods, upon which they move up and down. These boards are about 3 feet long, and half as wide (really a metre—39 inches; the precise size is not important). A supply of strong linen cloths about a yard long is required.

Two cleats to each board, to raise it from the next 1½ inch, and four frames 16 inches square, and 24 inches high, are necessary. One of the pieces of linen being well washed, is laid over one of the frames, and about four quarts of cream is turned upon it; the cloth is then carefully folded in such a manner, that the cream is completely inclosed; it is then placed on the press (as at E. D.), where it remains without any pressure for 10 or 12 hours. At the end of this time, the cream will be found to be solidified, and the cake may be removed from the frame, and put in press between the upper boards C; afterwards it is put between the boards at B, which are separated by a cleat for 1½ inch. Lastly, the cloth being folded several times upon itself, is placed at the highest board, where a number of bricks or other weights are used, to give sufficient pressure. At the end of two days, all the butter that the cream contained, will be found in the cloth. Nothing is said in the article as to the after treatment of the butter; in Europe salt is rarely used. In making cheese, the curd is placed in bags, and after some hours, these are folded, and the pressure continued as seen in the lower part of the press, both operations, butter-making, and cheese-making, being carried on at the same time. One of the chief advantages claimed for this method of making butter, is the avoidance of loss; in churning, a large number of butter globules remain in the butter milk, which have escaped the operation. The German authors claim, that the yield of butter is increased by 10 per cent. Another claim is, that the water is much more completely separated, and that on this account, butter thus made, will keep much better than that made by churning. It will strike most butter-makers, that this process has one marked fault—the length of

time during which the butter is exposed. Nothing is said about quality, but we should expect that it would not be improved by two days' exposure. On the other hand, the linen cloth, having its pores filled with liquid, would pretty effectively exclude the air. Another thing will strike a practical person, which is, the great amount of circumstance, and needlessly cumbersome appliances to accomplish the end in view. If butter only is to be made, two or three boards, and the necessary weights, would answer quite as well as the press. The pro-

A PRUSSIAN BUTTER, AND CHEESE PRESS.

cess is a very simple one, and it will be an easy matter for any one to test its efficacy. The article referred to, places much stress upon the importance of carefully washing the linens, and recommends that they be soaked for some hours in water, to which some Sal-Soda has been added.

### An Irrigating Gate.

A head-gate for lateral irrigating ditches, may be made very simply, by cutting out a piece of the middle of an inch board with a bevel cut, the slope of the cut being outwards, towards the lower, or down-stream side of the board. This is necessary to give a perfect clearance to the stream, and avoid adhesion of the water, which would lessen the flow. The board is built in the bank, and a foot-

A FLUME GATE.

piece is fastened under it, as shown in the engraving, to prevent the stream from working under the gate. The lower edge of the board and gate should be below the level of the ditch, and the board should be long enough to prevent the water from cutting around the ends of it. As a very small leak in water channels, will soon become a large one, if not guarded against, care should be exercised to avoid all danger of washing around the gate and joints in irrigating ditches as well as in dams.

Corn Markers are of nearly all sizes and shapes; but may be divided into two general

classes; those which make the marks with runners, and those that have pegs of some sort, which are drawn through the mellow soil. It is not necessary for us to decide which of the many home-made kinds is the best; but it is evidently the one that makes the best marks in the quickest time, and with the greatest ease. One drawn by two horses, which makes several marks or rows at a time, and permits the driver to ride, is certainly useful in large fields. We now only suggest here, that whatever kind is to be used, it should be looked to, and put in readiness for the work it is to do.

### A Barn Corn Crib.

On small country places, a multiplicity of buildings is neither economical nor desirable. A corn crib, however, is a necessary evil, and it may be provided for with much advantage, in a corner of the barn. An extra building is thus dispensed with, and the corn is where it can be reached very conveniently. The crib may be built in the corner of a barn, *figs. 1 and 2*, on the upper or lower floor, as it is the most convenient, and the wall may be opened and fitted with lath work, and protected by falling

Fig. 1.—BARN CRIB WITH DOOR.

shutters when necessary, as in figure 3. When the corn is thoroughly dry, the shutters may be closed.

### Are Pigs or Shoats Best for the Villager?

To the farmer who raises his own swine for fattening, and keeps over what he cannot sell, there is not much choice. It is his custom to fatten what he has on hand, and those are very often fall pigs when the sale is rather dull. The villager always buys the stock he wants to make pork of, and can generally put in his pen either wintered swine or spring pigs. Some always keep one or two pigs in the pen, and kill in the fall, and spring, putting

Fig. 2.—SQUARE CRIB WITH "MAN HOLE."

only pig pork into the barrel, and using only pig hams and shoulders. The great objection to this course is the increased expense and trouble of making pork in the winter, in all northern climates.

It takes a great deal of food to keep up animal heat in frosty weather and adds twenty-five per

Fig. 3.—OUTSIDE FALLING SHUTTERS.

cent to the cost of making pork and hams. When made they are no better than the summer made meats. The waste of the kitchen may better be fed to poultry than to swine, and there is no economy in keeping pigs to save these wastes. Others make better calculations, and buy pigs or shoats, as suits convenience early in spring, and feed all the pigs will consume until November, when they slaughter them in the first hard freezing weather about Thanksgiving. The choice between pigs and shoats depends mainly upon the prices. At the same price per pound shoats are generally preferred. But not infrequently they are much cheaper from the supposed superiority of pig pork. But there is not much foundation for this distinction, for the wintered pig weighing 80 to 100 lbs., and slaughtered at Thanksgiving, makes as nice hams and shoulders as the spring pig. His frame is already built, and other things being equal, the food consumed will give a larger amount of flesh. The hams will be larger, the pork thicker, the lard more abundant, and on the whole more desirable for family use. There is no difficulty in supplying all the hog products needed in a family; pork, salt and fresh, ham, bacon, sausages, and lard from the summer fattened shoat. With pigs, the hams and lard often give out long before killing time. Whichever are selected, feed regularly and abundantly all that they will consume. A squealing pig disturbs the whole neighborhood, and at the same time impeaches the wisdom of the owner.

### The Distribution of Labor on the Farm.

There are about as many kinds of farm management as there are kinds of men. To a certain extent this is natural, because there are so many different products of the farm, almost any one of which may be taken as the primary, and all the others thus become of only secondary importance. If butter is the leading "crop," the system of the farm will be of one kind; if wheat is the primary product, the methods pursued will be different from those for butter, and this again will not be the same as when sheep are the main source of the farmer's income. Circumstances of soil, climate, nearness to market, personal tastes, etc., will decide these matters. But whatever the system, whatever the leading crop grown—and we by no means believe that in all cases, or even in most cases, it is always better for a farmer to have a crop that is the leading one—there are certain general principles that should be binding upon one so soon as he becomes a farmer. He who by the soil would thrive, no matter what he is to make that soil produce, should so plan his work that there will be the least number of idle days, in fact, this means that there should be no days when the farmer has, as the common expression goes, to "kill time." Every worker of the soil, whether he owns or rents the soil, and is, therefore, working for himself, should put a definite market value upon his labor. This very many farmers fail to do, and overlooking this important fact, it easily and

naturally becomes a source of loss. It is as much to the farmer's advantage to have a full supply of labor for each and every work day, as for the day hand that gets his living from his daily labor.

The vital importance of the proper distribution of farm labor throughout the season—yes, the whole year—being accepted as a leading fact in profitable agriculture—the question is, how to make the most of it? In the first place it demands a careful planning of the whole season's work, if not the work for several years. This plan should account for work for not less than 290 days in the year—and the work of each of those days should be of such a character as to pay—not work to be done for the sake of doing something, but seasonable, profitable labor. This principle at once points towards a variety of farm crops, mixed farming, a rotation of crops, the ideal farming, and the one towards which substantial agriculture is tending.

A single example will suffice to illustrate and enforce the point. Let it be supposed that a farmer is growing roots, and that it is to his advantage to have the labor of the care of his roots distributed along through the season. Instead of putting his whole land into Swedes, and that in early summer when other labor is pressing, he can sow a portion of the land to Mangels as early as the ground can be worked, and later, after the Swedes are in, a part of the field may be put into Flat Turnips, which grow rapidly and must be fed so soon as grown. If soiling is practised the Flat Turnips may follow the early rye in July. In like manner there are many cases where the work that would otherwise come "all in a heap," can be distributed through the season, and "all hands" can be kept for several months and furnished with steady and profitable labor. The farmer who can best equalize his work and portion to each week and month its part, other things being equal, will be the most successful.

### A Farm Dog Kennel.

A correspondent from Morris Co., N. J., sends a sketch of a dog kennel, which is far more comfortable for the tenant than is usual with such buildings. It is common for the dog to be used as a homeless vagabond, and to be left to find shelter as he best can on the lee side of a fence, or in a hole under the barn. The dog may have sagacity enough to know when he is well or ill treated, and he may very reasonably lose his self-respect, and take to evil courses, such as prowling abroad, marauding and sheep killing, when not taught better, and provided with decent quarters at home. The conduct and attitude of a hardly used, half starved cur, is entirely different from that of a well fed, and decently kept dog, and every one who keeps a dog, should certainly take pains to treat him well, and train him respectably. A shelter of some kind should be provided, which the dog should recognize as his home, and the more comfortable this is made, the more contented and home-

A DOG-HOUSE.

keeping he will be; not to speak of the freedom from disease and vermin to be enjoyed. The kennel here described, is 7 feet long, by 3½ wide, and has two doors, one opening inwards, and one outwards, the latter door is provided with a bell, by which the owner can tell when the dog goes out at night. In summer one door may be raised for ventilation, but in the winter both should be let down.

### Salt for the Live Stock.

There are some who claim that the well known liking of our domestic animals for salt is due to education, that it is an unnatural appetite, that in a state of nature animals do not have salt, and assert their belief that it does more harm than good. It would be a sufficient answer to these persons that our animals are not in a state of nature, and what the pre-historic cow and horse had, or did not have, has nothing to do with what shall be given to their descendants. Those who

A HANDY SALT DISH.

write and talk so earnestly against salt are not many, and are usually people of notions, which they mistake for ideas. The great majority of cattle raisers and farmers are fully convinced that salt is necessary for the best health of farm animals, and practice what they believe. The amount of salt required is small, and it should be given at frequent intervals. If a little could be given each day it would be best, and if with the food, as we are accustomed to take it ourselves, it would be so much the better; but such a method is hardly practicable. Supplying salt once a week will answer, and this is the usual interval between saltings, if salt is given at all. Some special day or time in the week should be chosen as that for salting the domestic animals, and then it should not be allowed to go past without dispensing, what some one has termed, the "seasoning of the week."

An engraving of a handy salt dish is given herewith, which, simple as it is, better answers the purpose than any other that we have used or seen used. It consists of a low box made of hard wood with a thick bottom, and a handle made of hickory—a piece of heavy barrel hoop will do—nailed upon the sides as shown in the engraving. In dispensing the salt to stock in the open field, it should be so placed that all the animals can get their fair share, and again it should not be thrown upon the ground where it is largely lost, or if eaten it must be with a quantity of earth. Flat troughs should be provided even for economy's sake.

### Scrofulous Diseases in Domestic Animals.

An observing friend had a fat cow slaughtered, and finding in the lining of the cavity of the abdomen a large quantity—nearly a bushel—of strange objects, sent one of them, which is shown in the engraving. It proved to be a collection of Tubercular Tumors, of a kind often found in animals

TUBERCULAR TUMORS.

inclined to scrofulous diseases. They are due to a constitutional disease that is too widely prevalent in all kinds of our domesticated animals. Scrofula may be inherited, or it may be developed by the conditions of life that have an influence in lowering the vital powers—such as protracted derangement of the digestive organs, however caused—deficiency in the quality and quantity of food,

impure water, damp, filthy stables, defective ventilation, exposure to cold and wet and other unsanitary conditions. Animals in confinement are more liable to scrofulous disease than those of the same kind in a state of nature. Dr. Aitken says: "The stabled cow, the penned sheep, the caged lion, tiger, or elephant, are almost invariably cut off by scrofulous affections, no doubt due to deficient ventilation, and the abeyance of normal exercise of the pulmonary function." When the constitutional defect is inherited, the ordinary exciting causes of disease are liable to develop it, and it may assume a variety of forms according to the organ where the disease is localized. The heredity of the disease is often not suspected from the varied forms it assumes in different generations. The lungs of the parents may be affected when the disease is known as consumption, and the offspring may be affected with scrofulous swellings, marasmus, or wasting—or chronic bowel complaints. The disease may not show itself in the acute form for several generations, and may be even unsuspected until after death, when it may be recognized by tuberculous tumors that, as in the case under consideration, have not reached the stage to produce serious constitutional derangements. A careful selection of breeding stock should be made to avoid any hereditary tendency to the disease. When fully developed, the acute scrofulous complaints do not yield to any treatment, but run their course with the most unfavorable results. Prevention, by the observance of the best sanitary conditions, is the only means of counteracting the constitutional defect. We cannot too strongly insist upon pure air furnished in abundance to all of our domestic animals confined in barns, stables, etc., and fresh water and wholesome food at all times and places.

### A Manure Sled.

A sketch and description of a manure sled comes from H. H. Cooper, Lancaster Co., Pa., who thinks is "the handiest and cheapest sled he has ever seen." It is very simple in its construction, as

Fig. 1.—THE MANURE SLED.

shown in figure 1. The runners, *a, a*, can be of any desired length from 4 to 6 feet, and may be made of 3 by 4 pine scantling. The upright pieces, *b, b*, set in loose sockets in the rear ends of the runners, and can be easily removed. The chain for the attachment of the whiffletree is secured to the forward ends of the runners by staples put in at an angle of 45 degrees. The ends of the two runners are kept about 20 inches apart, by means of a spreader, *c*, placed between, and fastened to the ends of the chain. The manure is loaded upon these two runners, being piled up in a rather narrow ridge, (fig. 2). When the place is reached where the manure is to be deposited, the two standards, against which the manure is pressed somewhat tightly, are re-

moved. By starting the horse the sled is drawn from under the manure and the sled is empty, and, with the standards replaced, it will be ready for another load. "There is no trouble in turning as with the common long sled, and no second handling of the manure, to say nothing of the cheapness

Fig. 2.—METHOD OF USING THE SLED.

and simplicity of the arrangement." We are not aware that this simple farm implement is patented.

### Handle for a Cross-Cut Saw.

Mr. E. M. Goodale, York Co., Me., sends drawings of a handle for a cross-cut saw that is coming

Fig. 1.—A CROOKED SAW-HANDLE.

into very general use in that locality. The handle, as shown in figure 1, consists of a "natural crook" from a branch of some hard-wooded tree, in the form an inverted V, one arm of the crook being fastened into the saw clasp, while the other, which is in an inclined position, furnishes the handle for the operator. Figure 2 shows the method of procuring the handle from the fork of a small tree, or from the junction of one branch with another on a large tree. The use of this handle, our correspondent claims "saves the muscles of the shoulder, as a person using the handle can stand upright and saw, while with the straight handle the elbow must be kept level with the work." Any device that will make easier the work of sawing logs with a cross-cut saw will be welcomed by the many who have more or less of this shoulder-aching work to do.

Fig. 2.—SELECTING THE NATURAL CROOK.

**Revival in the Sheep Interest.**—There are at present more calls for the names of raisers of pure-blood sheep, than for a long time. A short time ago, a gentleman wished to know where he could purchase several car loads of the best Merinos, mostly rams, for shipment to the Southwest. Not only is there a revival as regards the number of sheep to be raised, but a strong tendency to grow only those of the best breeds. The "boom" in sheep-raising, as the slang of the day has it, is a healthy one, and one to be encouraged, moreover it seems likely to last for an indefinite period of time.

### Hay Sweeps.

We have requests for a plan of an implement to collect hay in a field and carry it to the stack or barn without loading it upon a wagon. This may often be done with profit if the ground is comparatively level and the stack or the barn is not far distant. The Hay Sweep, an implement that has been in use for some time, is one that well serves this purpose. The construction of the Hay Sweep may be learned from figure 1. It consists of a

Fig. 1.—A HAY SWEEP.

large horse rake, of the "revolving" sort, and a stout frame attachment, as shown in the engraving. Two horses are required to work the Sweep, one attached to each end and guided by boys upon their backs. When in action, the horses pass on each side of the windrow, the Sweep as it passes along gathering up the hay, as seen in figure 2. In this way a load of 500 pounds can be quickly gathered up and taken to the place of deposit. In unloading, the horses are turned back and the sides of the frame swung around, so that the back side of the rake becomes the front; the Sweep is then drawn away from the hay and is ready for another load. The dimensions for the construction of the Sweep here given are by John J. Thomas, in his work entitled: "Farm Implements and Machinery," from which useful volume we borrow the engravings.

Main scantling below, 4 by 5 inches and 10 feet long; the one above it same length and 3 by 4 inches; these are three feet apart, connected by seven upright bars 1 by 2 inches, and 3 feet long. The teeth are flat, 1½ by 4 inches, 5 feet long, or projecting 2½ feet each way; they are made tapering to the ends so as to run easily under the windrow....Each gate (end) consists of two pieces of scantling 3 inches square and 3 feet long, united by two bars of wood 1 by 2 inches, and a third at the bottom 3 inches square and tapering upwards, like a short runner....The whiffletrees are fastened a little above the middle of the gate, and should be so arranged that they may be raised or lowered so as to be readily adjusted. Mr. Thomas estimates that the Sweep may be made for \$6 or \$7. The rapidity and ease with which the hay in

Fig. 2.—THE SWEEP IN USE.

many cases is gathered with this implement renders it one of great service to many farmers, and at just that hurried time when every aid is a help indeed.

**Harrows and Harrowing.**—Harrows, of which there are a great number of styles, from the old "A" "drag," with its great wooden teeth, to the steel, square hinged harrow, and those of a still later form, provided with wheels, and a seat for the driver, all have a common object to accomplish—the thorough pulverization of the soil, and mixing of the various fertilizers that may have been added, and thus make an acceptable bed for the seed. The easy access of air to the soil, which follows from a thorough use of the harrow, is a matter of great importance, as upon it depends largely the formation of available plant food, and therefore the growth of

the plant, and success of the crop. The young growing roots—the ones that do most of the absorbing of food—can much more easily extend themselves through mellow soil, and reach the food that such a soil has in keeping for them.

### A Safe and Handy Poke.

A poke is often required to restrain breachy animals, and a sketch of what seems to be a very useful one is sent by Mr. F. Coney, Van Buren Co., Mich. From his experience with this poke he claims that it does not cramp the animal's neck while eating or when lying down. Also, that it thoroughly prevents jumping, and is perfectly safe. It differs from the ordinary poke in having the "bow" much longer, so that the block carrying the projecting pole is brought down to about the bend of the knees. Mr. C. says that this poke is so thorough in its action that it is troublesome for the animal to get over the "bars," as they are ordinarily let down for cattle to pass. "This is no objection, as the animal most likely received its first lesson in jumping by being forced through half open bars." A poke to be efficient should prevent jumping at

THE POKE ADJUSTED.

the lowest and weakest point in a fence, and the one shown in the engraving appears to be such an one.

### Links for Mending Chains.

It is often a great inconvenience to have a chain break, especially when many miles from home, or far from a blacksmith's shop, and the whole progress of the work comes to a standstill. A link like that in figure 1, is designed to come to the rescue in just such cases as this. Any blacksmith can make a number of them at a trifling cost, or one handy with the tools, can shape them himself. One or more of these can be carried in the pocket of the over-alls, or in some place about the wagon, plow etc., and thus the farmer, teamster, or lumberman, can go armed against breaks that are always apt to occur.

The engravings show the construction, and the method of their application. The importance of an easily adjusted link to a broken chain, has led the Ingalls Manufacturing Company, to invent a link for the purpose, upon which they have secured a patent. This link is a split one, with the two parts so united by a rivet, that it can be opened and adjusted to the chain, without the aid of any tools. This link is shown open in figure 3, and closed in figure 4. These handy links are now quite generally in the trade, and can doubtless be had at most hardware stores. A small sum invested in a supply of these, or of the home-made links, may save a much larger sum.

Fig. 1.—A CHAIN LINK.

### The Robin Question Again.

Professor S. A. Forbes, of the State Normal University of Illinois, in his elaborate report upon "The Food of Birds," published in the Transactions of the State Horticultural Society for 1879, gives a considerable space to the Robin. During the season 41 stomachs of this bird were examined and the insects found therein determined and placed in a tabulated form. During the month of March the food of the two specimens examined was very largely of grasshoppers and insects which feed up-

Fig. 2.—THE LINK IN PLACE.

on decaying vegetable matter. For this month nothing can be said against the Robin. In April eleven birds were killed, and the food was found to be much more varied than for the previous month. The record stands: caterpillars, 32 per cent; beneficial beetles, 23 per cent; scavenger beetles, 12 per cent. "These birds have apparently done very much more harm than good during this month, eating predaceous beetles, which would probably have destroyed many more noxious insects than were found in their stomachs." For May much the same record is made, showing very little in the Robin's favor. During June 55 per cent of the food comes under the head of fruits, and of this the largest part is cherries. Though the food of the Robin was largely fruits, there were many injurious insects found, and the difficult question arises of how to strike the balance. A quart of cherries cannot offset the same measure of injurious insects. "When a bird eats fruit the injury done stops right there; there are no accumulating consequences, but when it destroys a noxious insect, it checks the increase of the species, it destroys not only the one actual insect, but an indefinitely numerous host of potential ones." Prof. Forbes believes that this consideration settles the question, and that Robins are largely beneficial even in the month of June. In

Fig. 3.—INGALLS' LINK.

July there was, taking the insect food alone, 7½ per cent of beneficial insects, against 10½ per cent of injurious ones. "But a beneficial insect is far more beneficial than an injurious one is injurious." The amount of fruits eaten is large; a total of 77 per cent. "Even the most devoted friend of the Robin must admit that if these 14 were fair examples, the Robin is a nuisance in July." In August the bird makes a better record, and "a small margin of profit may be ascribed to his operations in this month."

In conclusion Prof. Forbes writes: "These 41 Robins taken together had certainly done, just previous to the time of their demise, fully as much harm as good, as far as we can judge from the contents of their stomachs....Temporarily we may place the Robin in the list of moderately useful birds, using every opportunity to increase our knowledge, and for the time being leaving him practically to himself."

Fig. 4.

**Stone-Boats.**—At no time in the year, are stone-boats so much in request as at this season, when there are so many heavy things to carry to and from the barn and field. The harrows, plows, bags or barrels of grain, and fertilizers, with other things that are often taken across plowed ground, are best conveyed on a stone-boat. Every farmer should have one or more of these low and handy vehicles, which costs but a trifle for lumber and bolts, and can be made in the shop on a rainy day. All things

considered, the kind made from two-inch plank, sawed with an upturned end, is as good as any. When the boat is not in use, it should be placed on two timbers, or tipped on edge, so that the bottom may not rest on the earth, and thus be kept from the wet, and preserved from otherwise rapid decay.

### The Line of Draught in Plowing.

One of the first essentials in good plowing is the adjustment of the clevis in the Line of Draught.

PLOW SHOWING LINE OF DRAUGHT.

No matter how perfect the implement may be in its construction and adaptation to the work required of it, if this adjustment is not properly made, it will not run on the sole and the furrow-slice will be irregular in form and imperfectly turned. Experienced plowmen, after repeated trials, will adjust the clevis to make the plow run level almost intuitively, without knowing anything of the principle involved in the changes in its position he finds it necessary to make. A knowledge of the various conditions that change the line of draught, and of the adjustments required in each case to make the plow run free, without a tendency to go too deep or too shallow, will, however, be of great assistance to those who wish to do the best work. The reasons for the adjustments required to make the plow run the proper depth will be readily seen from a close study of the accompanying engraving. The Center of Resistance in drawing the plow is a point (a) just above the sole. This point will, of course, vary slightly in position, being lower when the plow cuts a shallow furrow, and higher when the furrow is deeper. The line of draught is a line from the center of resistance, a, to the point, b, in the diagram, where the traces are attached to the collar. Now, to secure the free movement of the plow at a uniform depth, the clevis must be attached to the whiffletrees somewhere in this line, a-b. If the plow-beam is long, the end will be raised higher to cut this line—if the plow-beam is short, it must be lower for the same reason. If the traces are so lengthened that the team is farther from the plow, the weight of the collar remains the same, and the line of draught will then be represented by a-d, which cuts the clevis at a lower point, and a corresponding adjustment must be made to make the plow run as before. If the traces are shortened, the line of draught becomes a-c, the whiffletrees must be raised to the upper part of the clevis to keep the plow running at the same depth as in the other cases. When a smaller team is used, the point where the traces are fastened to the collar will be lower, and the effect upon the line of draught will be the same as that observed where the traces were made longer with the larger team. Every plowman knows that to hitch the whiffletrees to the upper notch of the clevis will make the plow run deeper, and to hitch in the lower notch will make the plow run shallow—and that to lengthen or shorten the traces will have the same effect. In each case, however, the adjustment consists in bringing the point of attachment in the clevis into the line of draught, which changes as the depth of the furrow varies, the attachment of the traces at the collar remaining the same.

**Cotton-Seed Meal** is a very concentrated food, and in using it this fact must be kept in mind. A ton of it contains about 37½ pounds of Potash, 50 lbs. Phosphoric Acid, and 75 lbs. of Nitrogen. It is highly nitrogenous, as the analyses show, and therefore should be used with substances rich in starch, or like materials, which contain little or no nitrogen. Two pounds of cotton-seed meal, is

enough to feed daily to a cow or a horse; smaller animals, should have proportionally less. Fed in the quantities given, there is no danger of its doing any injury, but only good to the animal system.

### Hints and Helps for Farmers.

**A SELF FASTENING BOLT.**—A simple and handy bolt is shown in figure 1, the important feature of which is the curved end. This end is so looped, that it will pass over the clasp a, when the loop is held upright. After the curved end of the bolt has been shoved past the clasp a, thus bolting the door, the bolt turns down of its own weight, to the position shown in figure 2, in which position it cannot be pushed back, because the lower part of the clasp a is longer than the upper. If it is desired to lock the door, this can be done by

having a hole in the lower part of the clasp, through which the stem of a common padlock can pass above the curved end of the closed bolt.

**A MENDING CLAMP.**—One of the handy things on a farm, is a clasp to hold firmly together the broken

Fig. 1.—BOLT OPEN.

pieces of harness, halter, etc., while being mended, like that shown in figure 3. The clamp consists of two curved hickory strips, which are nailed to a

Fig. 2.—BOLT FASTENED AND LOCKED.

small square block by one end, the opposite ends pressing upon each other with some force. The ends where they come in contact, should be so shaped that they will meet squarely, with as large a flat surface, as the thickness of the material will allow. When in use, the clamp is held between the knees, so that any additional pressure may be easily given. The implement is often made from portions of two barrel staves, which is much easier than to work out the hickory pieces, and for most purposes for which the farmer needs a clamp, made in this way will answer about as well.

Fig. 3.—MENDING CLAMP.

**A LITTER BASKET.**—There are many occasions upon the farm where an ordinary basket is far too small for the best service. The one shown in the engraving below (fig. 4), is designed to meet such cases, but the writer has specially in mind the use of it in carrying green fodder from the field to the

Fig. 4.—A HANDY LITTER BASKET.

stable, where it is to be fed, provided the distance is not very great. The Basket consists of a large open, hoop-pole box resembling a crockery crate—

but not so heavy, with two bars, fastened upon the sides to serve as handles by which it may be carried by two persons. Such a basket can be used for gathering various kinds of roots, cabbages, etc., and, in fact, very many things upon the farm.

**A COW CURRY COMB.**—"R. E.," Snyder Co., Pa., sends a sketch of a curry comb and brush for use in the cow stables.

It is made of broom-corn, for the brush part, and two pieces of wood 6 or 7 inches long for the "head" fastened together by two bolts, with the broom-corn between them, as is shown in figure 5. A handle of any desired length is fastened to the middle of the brush. Mr. E. likes it better than any other curry comb that he ever used with his cattle.

5.—A COW CURRY COMB.

**ANOTHER WAGON JACK.**—No doubt that so long as wagons run, they will need to be oiled or greased, and to do this, jacks will be used. A subscriber adds still another to our collection, in sending a sketch of one he has used for a long time, and which he thinks superior to many he has seen. The engraving, figure 6, gives the method of construction of this jack, and it needs but little explanation. The base is large, which is an important point in an implement of this kind. A single upright piece, a lever with a few notches, and an iron key, with a couple of bolts to secure them to the standard, are the materials required to make the jack. The method of operation is simple, the dotted lines showing the different positions of the lever.

### Sheep Washing.

It is a question in the minds of many wool-growers as to the practical utility of washing the fleece while it is still upon the sheep's back. A deduction—usually one-third—is made by the wool-buyers from the weight of all unwashed wool, and in most cases this is not far from the loss which the fleece would sustain in the process of washing, if it is done with the average amount of thoroughness. Nevertheless, the practice of washing the sheep is

Fig. 6.—A JACK FOR LIGHT WAGONS.

very general, and if there is no return in money for the labor of washing, there is the satisfaction of having cleaner wool to work with when shearing.

The common method of washing is to select some favorable place in a brook where the water is about 3 feet deep, the bottom hard and gravelly, and the current moderate, and then build a pen of rails sufficient to hold a large flock, and provided with a narrow opening towards the stream. Into this pen the sheep are driven through an opening, temporarily made for the purpose, at the rear. One man, perhaps aided by a boy, tends the flock and passes the sheep to the washers who are standing in the stream. The sheep should have been previously tagged and freed from all large soiled clots. The washing should not be done until the water has become so warm that the sheep may not be chilled and injured. Special care must be taken with old or sickly sheep, and ewes that are still with lamb. An exposure of the sheep to a warm rain

the day previous to the washing is an advantage, as it softens and loosens the dirt and renders the washing easier and more thorough. As the sheep are washed they should pass out upon a clean, grassy slope that rises gradually from the stream, otherwise the water-laden animals may fall and soil their fleeces. After washing, if the weather should suddenly turn cooler, the flock should be provided with shelter, to prevent their taking cold, as they would be very likely to do. From the time of washing to that of shearing, two weeks or so, the sheep should be kept in a pasture that is free from any bare ground, overhanging banks, or steep side-hills, so that the wool may be kept clean.

A second method of washing, which is employed when the stream is small but somewhat rapid, is to arrange a spout for the passage of the water, and hold the sheep under the end—the water flowing upon the animal. In this way the washer does not go into the stream, and if provided with rubber boots and apron, may keep himself comparatively dry. The washing by this method is very thorough as there is a stream of clean water constantly flowing into and through the wool, and carrying off the impurities as they are removed from the sheep.

### Bogus Bermuda Grass.

#### Serious "Official" Blundering.

A friend in Marshall, Texas, wrote a while ago, that the same mail which brought him the February *American Agriculturist*, containing an article which stated that Bermuda Grass was not known to produce seed in this country, also brought him a package of "Bermuda Grass Seed," from the Department of Agriculture at Washington! Naturally he was in a quandary, and inclosing a sample, said: "Please tell me if this is the seed, if so, is it probably brought from some other country?" We opened the parcel;—with all our faith in the capacity of that Department for blundering, we could hardly believe it. It did not seem possible that any one not entirely daft, could have sent this for Bermuda Grass. We wrote to our Texan friend for the label sent with the seed, and in response to this request he sent not only the label, but the parcel as it was received. There could be no mistake about it—at least not on his part. The label reads thus:

"Department of Agriculture.

### BERMUDA GRASS.

Note and report, soil, culture, time of ripening, quality, and quantity of crop. This is required of all persons receiving seeds, as a condition of the distribution."

The bag contained about a quart of broken spikelets, a whole one of which, of the natural size, is shown in figure 1. This grass, though well known to hotanists, is so little known to people in general, as to have received no common name—at least, none is given in the works on southern hotany, nor have the southern friends of whom we have inquired, been able to learn of one. We are therefore confined to its hotanical name, which may be called an uncommon one, so far as length is considered—*Stenotaphrum Americanum*. Generally when we know the derivation of such a name, its meaning helps us to remember it, but in this case it does little good to know that *Stenos* means "narrow," and *Taphros* means a "groove," when the "narrow groove" is upon a part of the flower quite hidden from sight, and so small that only a glass will show it. As to the specific name, *Americanum*, that can hardly be regarded as descriptive. We do not take sufficient space to figure the whole plant, as the flowering portion is the characteristic part of it. It has extensively creeping stems, from which arise flowering stems about a foot high, bearing one to four such spikes as that in figure 1. The structure of the spike is quite unlike what we are accustomed to see in grasses; that portion which holds the flowers (and seeds), is thick and flattened, and the flowers are hidden in little depressions, or excavations in its substance—a structure so unusual, that it would arrest the attention of any observing person. Compare this figure with that of the spikes of Bermuda Grass in figure 2, both being of real size. Can any

two grasses be more unlike? Yet the Department of Agriculture of the United States, sends this over the country as Bermuda Grass! When Newton was at the head of the Department, a friend of ours was in the office on some business, and saw a box, labeled "*Echium vulgare*," and on asking what that meant, he was informed that it was "the seeds of a new honey plant just imported from Europe," which was about to be distributed for trial as bee pasture. Our friend, thinking that there was already quite too much "Viper's Bugloss," or "Blue Devils" in the country, made such a vigorous protest, and brought such strong evidence upon the point, that the country was saved this scattering broadcast one of the worst weeds known to our agriculture. It appears that the Government Seed Shop has not improved in all these years. Let us say here, that the sending out of this stuff for "Bermuda Grass," could not have happened had the Botanist of the Department been consulted—and the very fact that it is done, shows that he was not consulted—for he, being a man of science, would have protested against it. But what is the *Stenotaphrum* really? Not being Bermuda Grass, what is it good for? will he asked. This is a point upon which we have not been able to get any direct information. Doct. Porcher, in his excellent work on "The Resources of Southern Fields and Forests," does not mention this species of grass,

which is in itself strong negative evidence, for scarcely any vegetable product of even doubtful utility, has escaped this industrious author. Chapman says nothing as to its uses, and Elliott, (1821), whose descriptions are much more in detail, and who rarely fails to notice the popular reputation a plant may have, if useful or otherwise, says nothing of this, nor do recent inquiries add to our knowledge. The plant is described as growing near salt water, from South Carolina to Florida. If a grass found within the influence of salt water, should he found of any value in cultivation, it would be something remarkable. But that is not the question, and does not affect the fact that the Government Seed Shop is conducted with a lack of accuracy, a wicked, blundering stupidity, that would ruin any one legitimately engaged in the seed business. A salt-water grass, not its seeds proper, but its seed clusters, of no known utility, is sent over the country at public expense by the Government mails, with the Government label, under a false name, pretending to be the seeds of a grass, which, under certain conditions, and with proper management, has real value, but which has never yet, so far as our most experienced botanists have learned, produced seeds at all in this country. This Government distribution of seeds is a sham and a farce. Sustained under the plea that it introduces new and rare varieties, it really supplies squash, tomato, and other common garden seeds, that

Fig. 1.—"BERMUDA GRASS" (*Stenotaphrum Americanum*) OF THE U. S. DEPARTMENT OF AGRICULTURE.

the many have to buy, to the friends of a few Congressmen. When it undertakes to give out a novelty, it is quite apt to send seed of a tropical plant, with no explanation, to Northern Minnesota,

or make some other blunder. But this Bogus Bermuda Grass Seed, is the most glaring example of the utter ignorance, of the entire lack of appreciation of the importance of accuracy, that has come to our knowledge. It is time, if this seed business is to be continued, that it cease to be carried on to

Fig. 2.—THE BERMUDA GRASS (*Cynodon Dactylon*).

the detriment of the farmers of the country. How many, who having read of the value in some localities of Bermuda Grass, will plow, harrow, sow, and watch and wait, and if they get any return, will have only what is likely to be a useless salt-marsh grass—at any rate not Bermuda Grass. Thus an error goes out with Government sanction, which will not be rectified in years. Instead of striving for a seat in the Cabinet, or giving hanquets marked by the conspicuous absence of nearly all of the hidden guests, the head seedsman had better get some one in his shop who knows Bermuda Grass, that its hotanical name is not *Stenotaphrum Americanum*.

### Some of the Newer Grapes.

It is interesting to look back 12 or 15 years in our volumes, and see how largely they were occupied by articles on grapes and grape-culture. There seemed at one time danger of a second "multicaulis mania," so generally did grape-culture occupy public attention. The sudden cessation of this interest is one of the most curious incidents in the history of our fruit culture. The inroads of the Phylloxera, though unrecognized, had much to do with the collapse, but not all. Our people in this, as in many other things, had a "zeal beyond knowledge," and that cooling off, which in such cases is sure to come, took place in this instance with a most surprising suddenness. Though grape-culture has, since that time, been remarkably quiet, it must not, on that account, be inferred that nothing has been done. In fact, there has probably been more real progress in these last 12 years than in all previous time. Formerly it was thought that progress consisted in producing new varieties of grapes, and the great point was to get the grape. We already had the "grape for the million," but our leading grape-men strove to find one grape for "all the millions." As we look back upon it how droll it all seems. There were several who claimed to have the grape, and how perfect (in its producers eyes at least), that grape was! To ask a question implying that the grape had a fault, was as great an offence as to speak disparagingly of the owner's wife. The grape-safety of the nation was to hang upon the grape, and it is astonishing how many of them there were. Where are they all now? We have learned much since those exciting times. When we learned that there was not, and in the nature of things could not be, one grape for the whole nation, a long step was made forward. When that point was admitted, the occupation of those who had the grape was gone. The Phylloxera was a dreadful scourge, but it taught a most important lesson, that there were grapes—and grapes. Grape-growers did not

recognized the fact that while Nature had given us several very distinct species of wild grape, they had been working, with remarkably few exceptions, upon the varieties of one species and hybrids from them. The Isabella and Catawba, the Iona and Walter, the Concord and Ives, and a long list of others that have had their season of popularity, were all derived from one and the same wild species, and consequently partook, more or less, of the peculiarities of that, whether those were desirable or otherwise. The general recognition of the fact, and working upon the knowledge that there were, at least, three other species of native grapes, the varieties of which might be valuable, was the next forward step in grape-culture. The varieties we have referred to are derived from the common Fox Grape of the Atlantic slope—the *Vitis Labrusca* of botanists. Besides this there are *Vitis aestivalis*, the Summer Grape, *Vitis cordifolia* (sometimes called *riparia*, for reasons we need not give here,) the Frost Grape, and *V. vulpina*, the Southern Fox, or Bullace. This last is restricted to the far Southern States and need not be considered, but the other two species have proved mines of horticultural wealth, which have amply repaid the thorough working they have received in the past few years. We would not be understood to say that varieties of these species were not previously known in cultivation, as every one familiar with grapes knows better; but, that it is only recently that an earnest effort has been made to seek out new varieties of these, and to improve them by the production of new seedlings. We have turned out of the old ruts and are running in new tracks. Not only do the species mentioned differ in their fruit, but they are unlike all through, even to the texture of the wood and the ease with which they may be propagated from cuttings. As stated in another article, the grape-louse—Phylloxera—is not destructive to all grapes alike, there being certain varieties that are so little affected by the scourge that they are practically Phylloxera-proof. Upon this fact, it is not too much to say, rests the future of grape-culture in this country, and the search for varieties which, while they resist the Phylloxera, shall be equal to the older kinds in the quality of their fruit, has led to the great recent improvements in grape-culture to which we have referred. We had varieties before of which the fruit was good enough, well nigh perfect, but we couldn't get it, no matter how many vines we had; there was "mildew of the leaf," there was "rot of the berry," and there was "the vine didn't do well with me"—another name for Phylloxera, that stood between us and the fruit we knew to be so excellent. It is largely due to the devoted grape-growers of Missouri, and to Mr. Ricketts, of Newburgh, N. Y., who has been at work in the same direction, that we now have several, with the promise in the near future of several more, varieties of grapes, the fruit of which is of excellent quality—and, what is more to the purpose, the vines are thus far, without the drawbacks that have made grape-growing too often little else than a series of disappointments. While we anticipate gratifying results from the introduction of new varieties derived from the *aestivalis* and *cordifolia* species, the former being especially suited to the Southern States, we would not forget that great improvement has been made in those derived from *Labrusca*. Because other classes of grapes are coming to the front, it will be a long time before these will go to the rear, especially as table grapes. In this class we find some of our very best and our very worst as to quality, and there is no uniformity as regards their ability to resist mildew, Phylloxera, etc. Among the newer varieties especially noticeable

are Brighton, Highland, Jefferson, Moore's Early, and Storm King among dark grapes, while in whites we have Duchess, Pocklington, Niagara, Lady Washington, and Prentiss. Among new

are generally followed in Missouri, and shows how to convert the fruit into wine, is especially valuable for the information it gives on the newer grapes of all classes. We give two engravings from the book,

showing two of the newer varieties, one of a peculiarly western type, the Elvira, and the other, the Prentiss, one of the recent eastern additions to the grape list.

THE ELVIRA belongs to the class of grapes derived from the species *cordifolia*, and is very interesting, as showing that a faulty, almost worthless variety, may produce a seedling of great excellence. It was raised by Jacob Rommell, of Mo., and is a seedling of the Taylor. The parent is chiefly noticeable for a wonderful extent of vine, and a corresponding scarcity of fruit. The fruit is well enough, but the berries are but few in a cluster and small. The Elvira—well, to hear our Missouri friends talk, brings back the days when the originators of the Iona, the Walter, set forth their merits, with this difference however: those grapes had no faults, while the Missouri people admit that the Elvira has just one; The bunch is so compact, that sometimes a rain coming after a drouth, causes the berries to crack. It is a white grape of medium size and great beauty, and of excellent quality for both table and wine; perfect hardiness, entire freedom from disease, great productiveness, and ease of propagation, are claimed for it. The shape of the bunch is given by the engraving, with which is a separate berry, to show the actual size.

THE ELVIRA GRAPE.

grapes should be included the wonderful collection raised by Mr. Ricketts, a few of which have been offered, but many choice treasures are yet in reserve. Indeed, so many have been the additions to the list of grapes that a new work on grape-culture was needed, if only to record and describe these, as they have all appeared since any of the standard books were published. Prof. George

THE PRENTISS was raised by a gentleman of that name, in Western New York, and is from the Isabella. If bad qualities were always transmitted, this should have its share, but, on the contrary, the vine appears to be exceedingly healthy. This is also a white grape, of medium size in bunch and berry, of good quality, and a toughness of skin, that makes it a most excellent market fruit. Its

A NEW WHITE GRAPE—PRENTISS.

Husmann, of the State University of Missouri, has given us such a work,\* and all who know anything of grapes and grape-culture will concede his ability to do so. This work, while it gives the author's methods of growing and training the vine, which

\* American Grape-Growing and Wine-Making, by Prof. George Husmann. New York: The Orange Judd Company, 245 Broadway. Price, sent by mail, prepaid, \$1.50.

productiveness is shown in the engraving, and is something wonderful. As we saw and handled the vine from which the photograph was taken, we know that no bunches were tied on for effect; indeed, when we say that it was exhibited by Mr. T. S. Hubbard, of Fredonia, N. Y., the assurance is unnecessary. It was wonderful as a specimen of fruitfulness; but no vine should bear so much.

has been made in those derived from *Labrusca*. Because other classes of grapes are coming to the front, it will be a long time before these will go to the rear, especially as table grapes. In this class we find some of our very best and our very worst as to quality, and there is no uniformity as regards their ability to resist mildew, Phylloxera, etc. Among the newer varieties especially noticeable

### The White Moulds on Plants.

A number of our cultivated and other plants are often attacked by members of a small group of Fungi, which, from the prevailing color of the blotches and spots they produce, are commonly spoken of as the *White Moulds*. The mustards are especially subject to these moulds, their stems (a

portion of one is shown in fig. 1) frequently being almost entirely covered with the white spots, which have been likened to streaks of white-wash, and not without good reason. The Cabbage, Cauliflower, Shepherds' Purse, and a number of other plants belonging to the Mustard Family, are subject to these pests. One species of the *White Moulds* is common on the Salsify, or "Oyster Plant," and in some localities "it is so abundant as to excite fears that the crop might be destroyed." Figure 2 shows an enlarged view of one of the spots of figure 1. It is seen that the epidermis, or skin of the mustard stem, is ruptured and forced back by

a mass of white-colored substance, which arises from the interior. This substance consists of a vast multitude of spores which are white and closely packed together. A cross-section of one of these

small spots from a leaf, is shown in figure 3, from which a clear idea of the nature of the mould may be gained. The skin of the leaf is shown as ruptured and turned back—the substance of the leaf below is seen to consist of oval cells which are shaded or dotted; those at the lower portion being regular in their arrangement by the side

2.—WHITE SPOT MAGNIFIED.

The fungus itself consists of minute threads, which may be seen passing between the leaf-cells and ending at the point of rupture, in rows of nearly spherical bodies, which extend upwards and are exposed to the open air. Two of the rows of spores are shown still more highly magnified at the right of figure 3, with the attachment to the thread at the base; some new rows of spores are beginning to be formed. The slender threads which pass through the substance of the mustard, or cabbage plant, act as roots for the purpose of taking up nourishment, and it is only after these threads, or filaments, become numerous and well established, that the fungus turns its attention to the production of spores. In this respect fungi are like all other plants, first they accumulate a stock of nourishment and then devote it, or a large portion, to the

Fig. 3.—CROSS-SECTION OF MOULD SPOT. Fig. 4.

propagation of the kind. The white spores, which are formed in such large quantities, are for the rapid increase of the mould; and they are carried by wind, rain, etc., to some new place on the same or another plant, where they germinate and grow, and produce a new spot in the course of a few days, thus spreading the disease with great rapidity. Besides the spores just described, which we have seen are produced in rows upon protruding filaments,

and are for immediate growth, there is another kind which is formed by a slow process by the union of filaments down in the substance of the plant upon which the fungus is growing. This second kind of spore is much larger, provided with a thick, firm coat of a dark color, which is variously marked upon the surface. A considerable portion of the growing season is required for the perfection of spores of

Fig. 5.—WINTER SPORES AND THEIR MOTILE SPORES.

this kind, and they can be found in autumn always within the substance of the plants. They do not germinate at once, but remain dormant through the winter, and grow the following spring. The germination of these winter spores, as they may be called, is peculiar. The contents divide up into a large number, sometimes as many as a hundred, small bodies, each of which then grows and produces a separate plant. Figure 5 shows one of these winter spores, also one producing a multitude of small bodies, each of which is provided with two minute hair-like threads, and capable of motion. One of these little bodies—motile spore—is shown greatly magnified near the center of the engraving.

Up to the present time the injurious effects which have resulted from the *White Moulds* have been small as compared with those from many other fungi. From the general similarity of the members of the group in hand to the *Grape Mildew*, the treatment should be the same, namely: the use of Flowers of Sulphur, dusting it freely upon the plants so soon as there are any signs of disease.

A word can be said in favor of the *White Moulds*, in that one species is very fond of the common Purslain or "Pussley," and often attacks it so vigorously as to endanger its life. For this no one will complain. Another member is a lover of the "pig weeds," and helps to keep them in check. If we could induce all fungi to grow only upon our weeds it would be a strong point gained.

### The Great Enemy to Grape Culture—Phylloxera.

Since the first discoveries concerning *Phylloxera*, we have through one cause and another said but little about it. Indeed, since we had an article on the subject a vast number have taken up grape-growing, multitudes of new readers have come to our pages, and it seems necessary to give a brief account of it. *Phylloxera* is a plant-louse, the name, which stands for a genus of these insects, is derived from Greek words, meaning a leaf, and parched, from the scorched appearance that oak-leaves assumed from the attacks of another and an earlier known species. The full name of the one in question, that which preys upon the grape, is *Phylloxera vastatrix*. It is an American insect, and was a cause of serious losses to our grape-growers long before its existence was known or even suspected, and passing to Europe completely devastated the vineyards of some localities, and where wine-making is an important industry, caused losses only to be estimated by millions of dollars. Those familiar with grape-vines must have noticed—especially upon the Clinton—leaves studded with small warty looking galls, as in fig. 1, which sometimes present a very pretty appearance. Some seasons these are very abundant, and again rare; these, if cut open and examined with a magnifier, will be found to contain an orange-colored insect and her eggs. Figure 2 represents one of these galls thus divided, the cross line giving the real size. This is one form or type of the insect, which lives only upon the leaves, and does comparatively little damage. Another type of the insect inhabits only the root of

the grape-vine, and as this is the most important from the injury it is capable of inflicting, we will not notice the other any further at present, beyond saying that it is called the *Grape-Gall-Louse* or *gallicola*-form of *Phylloxera*. A vine is observed to make a poor growth, the next year the growth is still less vigorous, the leaves turn yellow, and that year or next the vine dies outright. If the vine be dug up, it will be found to have no fibrous roots, and after its death it is very likely that no cause of the trouble can be found. If, when the symptoms of failing first appear, the vine be dug up and its roots examined, they will be found to present the appearance shown in figure 3, and a magnifier will allow the cause of the trouble to be plainly seen. In figure 3, a small fibrous root, one of the rootlets, by which the plant feeds, is shown at a. Upon the portions of the larger roots, marked d, d, d, great multitudes of minute root-lice will be found, and elsewhere on the root-fibres; these when young and tender are punctured by the insects which suck away at their juices, the results of their injuries being seen in the swellings and knots formed upon the root-fibres, as shown at b. After they have exhausted one, they go to others, and this rootlet soon begins to decay, as shown at c, and before

Fig. 1.—THE LEAF GALLS.

long the whole root-system of the vine is completely destroyed, and the vine of course dies. This being the form of the injury, let us briefly describe the insect which causes it. Like many related insects, the *Phylloxera* has its winged and its wingless forms, and its females are capable of reproduction for several generations without the presence of males. The insect passes the winter in the dormant state upon the roots of the vine, as larva, which is much like the root in color; when the growth of the vine starts in spring, these rapidly reach the mature wingless state, and commence laying eggs. In figure 4 is given a, the back, and b, the side view of these wingless females, magnified, the real size being shown at the left hand of b. These eggs hatch and produce other egg-laying females, and five or six generations of them follow on, the insect thus multiplying rapidly and preying upon the growing root-fibres. About midsummer, some females with wings are produced, and these make their way to the surface, and fly away to found new colonies, and this continues, the production of winged females, until the growth of the vine ceases in the fall. A view of a winged female is shown at figure 5, of course greatly magnified.

Fig. 2.

These winged females carry the trouble from vineyard to vineyard, and it is believed the wingless ones make their way over the surface and through crevices from vine to vine. There is much that is interesting in the history of the insect, such as the production of both sexes after several generations, which start the race anew for several continuous generations of egg-laying females, and that the root-lice may produce the gall-lice upon the leaves, but we can not occupy space with these. The point with the grape-grower is, to know the disease; what causes it, and the remedy. Here, of remedy proper, there is none. Various applications have been suggested, but they are impracticable. The root-lice attacks all forms of the European vine (*Vitis vinifera*), and is sadly destructive to it, the climate in many European wine countries being especially favorable to the development of the insect. The

capital discovery has been made that all varieties of American grapes are not equally injured by *Phylloxera*, and that while it is almost impossible to cultivate some, on this account, there are others that may be regarded as *Phylloxera-proof*. This dis-

Fig. 3.—ROOTS OF THE GRAPE.

covery and its practical application, in the production of varieties that produce good fruit above ground, and can in their roots resist the destructive little louse, have given new life to grape-culture in this country. Already several varieties are now known that do both, and still others are soon

Fig. 4.—WINGLESS FEMALES.

to be expected. Not only has the influence of this discovery revived the hopes of our vineyardists, but it is likely to prove the salvation of grape-culture in Europe. Thousands, if not millions, of our *Phylloxera-proof* vines and cuttings have gone

Fig. 5.—WINGED FEMALE.

abroad to be used as stocks in their vineyards, upon which, by grafting, to establish their grapes on invulnerable roots; and as *Phylloxera* has already appeared in California, where the European grape is so largely cultivated, the vineyardists there must soon adopt the same measure of safety. Thus America, which sent the insect which at one time threatened to make barren the vineyards of Europe, has afforded the only practical relief. The engravings here given are from the Missouri Reports of Prof. C. V. Riley, whose labors in relation to this injurious insect alone would accord to him the highest rank as a scientific and practical entomologist.

### Another Orchard Lamp.

In March last we gave in an account of the North Texas Pomological Society a description of a lamp adopted by the Society, to be used in trapping night-flying insects. After that paper had gone to press, we received from the Secretary, T. V. Munson, Esq., a letter, stating that he had been experimenting with the different lamps that had been presented to the Society, with a view of learning which was the most economical of oil, and would best hold its flame in the wind. He sends a drawing of one which he finds preferable to the lamp figured in March, and which he had selected as probably the best without having tested it. The apparatus here given has a common brass hand-lamp, with a slotted burner; it has no chimney, but is provided with a cylinder of brass (c) open at both ends, placed over the burner to shield it from side gusts; the cylinder is perforated around the lower margin, to allow of better ventilation and prevent heating. The lamp stands in a pan of water upon which a little oil floats. A stationary double shade (s) is attached to the pan. Mr. M. estimates the cost of the whole at \$5 per dozen." This wholesale destruction of insects is a matter that needs careful observation and study, and in presenting one of the methods by which it is proposed to accomplish this, we by no means give it full approval. In catching insects the light attracts and the water drowns all night-fliers alike; many thus caught will no doubt be injurious, others will be, so far as known, without any direct relation to our fruit and other crops, while others still may be positively beneficial as destroyers of other and harmful insects. It becomes a problem whether the capture of beneficial insects is not a greater injury than the taking of the noxious ones is productive of good. Experiments are needed before this matter can be decided, and it is likely that the results will be very unlike in different localities and in different seasons. We hope that the wide-awake Texan pomologists will aid in settling this question.

AN INSECT LAMP.

### An Asparagus Bed.

If any farmer were to read the directions given in the older works for making an Asparagus bed, he would at once conclude that Asparagus was a luxury not for him. A pit was to be dug, and oyster shells or brick-bats put in for a foundation; then numerous loads of manure were to be buried by trenching, and so much circumstance attended it that ordinary persons were frightened at the labor and expense. But of late years our garden-books do not copy English methods, and in nothing is the change for the better seen more distinctly than in Asparagus culture. Any one who can set out tomatoes can plant an Asparagus bed. The first thing is, to get the plants; good strong plants a year old may be had of most seedsmen. If one prefers, he can raise the plants; the seed is to be sown in a rich bed just as beet seed is sown; make rows 15 inches apart and an inch deep, distribute the seed evenly, and cover; when the plants are well up, thin to three inches, and keep clear of weeds all the season; the plants may be set next fall or the following spring. Those who buy the plants will gain a year; they are usually advertised in our columns. For family use the distance of planting varies. Where there is a plenty of room, rows three feet apart, with the plants a foot distant in the row, is better than nearer. Choose good

garden soil, and set the plants so that the crowns will be at least four inches below the general surface. At planting, give each root a spadeful of fine manure or compost, and trust to annual manurings to keep the plants in a productive condition, instead of the old method of manuring once for all future time. During the season keep the bed well cared for, the soil loose and free from weeds. As a general thing, the plants should grow two years before cutting. There are several new varieties now offered. Smalley's Defiance, Giant, and the Colossal are the most prominent ones.

### A Ticket or Label Holder.

Those who exhibit fruit, wish visitors to know whose it is, and those who visit exhibitions wish to know whose and what the fruit is. Yet every one who has had much to do with exhibitions, is aware that after a dish is handsomely filled with specimens, there seems to be no place for the ticket. If put upon the fruit it hides a portion of it, and disfigures what would otherwise be a handsome object. If the card is laid upon the table it is very apt to be displaced either accidentally, or by those persons who use their fingers to aid their eyes. The necessity for some contrivance to attach the ticket to the plate and to the dish led to the invention of one several years ago by our friend, E. W. Buswell, Treasurer of the Massachusetts Horticultural Society. Now another contrivance for the same purpose comes to us from Mr. Peter Rudell, Grand Rapids, Mich., who, without any knowledge of the other, has contrived the device shown in the engravings. The affair is made of brass wire, which has considerable elasticity, and is bent in the shape shown in figure 1, by which it will be seen that the wire is all in one piece, and so bent as to afford at one end a clamp to clasp the edge of the dish, while the other holds the card or label, which is placed between the ring and the straight piece of wire shown as crossing the ring. If desired to hold the card still more securely, that end may be made sharp and bent at right angles to form a small point to penetrate the card. A card once put in place in this holder is secure against removal by any passing wind, and is held up where it is seen to the best advantage, by all who wish to be informed of that which the label is to represent. With a bit of wire of a size a trifle larger than the one shown in figure 1, one can, by following the engraving, soon learn the bends necessary to give it the proper form. Figure 2 shows the way in which the affair is used; it holds the label well away from the fruit, allowing both that and the fruit to be seen. Mr. R., by freely giving them this little invention, has placed exhibitors of fruit and managers of exhibitions under obligations to him. Now that the

Fig. 1.—SHOW-CARD HOLDER.

Fig. 2.—THE CARD-HOLDER IN USE.

spring shows are at hand, those in charge of them should provide a supply of these useful and convenient affairs, as Strawberries are, of all fruits, the most easily disfigured by having large paste-board labels laid upon them in the ordinary way.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### A Thermometer Frame.

Aside from the pleasure many persons seem to derive from the frequent consultation of a thermometer, apparently to ascertain whether they are hot or cold, it is of real use in giving an accurate knowledge of the heat of a room, and thus aid in keeping it of a proper and even temperature. Thermometers are now so cheap, and at the same time sufficiently accurate to serve as an index of temperature, as to be within the reach of all. We say "index," because it is a well-known fact that a person, of himself, is not able to judge of the heat or cold of a place with any great degree of accuracy. What is warm to one person may not be so to another—the sensation of heat and cold depending so much upon the temperament, personal health, previous exposure, etc. But we did not intend to discuss the uses of the thermometer so much as its surroundings. A plain thermometer—plain as to its scale and figures, and plain as to its mounting—is usually likely to be better than any fanciful one, and the best to buy. Many ladies with a taste for home decoration will contrive to

A NEAT THERMOMETER FRAME.

unite the useful with the beautiful, and provide some kind of a pleasing background against which to fasten the thermometer. The accompanying engraving suggests a form of frame which may be constructed of a variety of materials, and in a number of ways, allowing the taste to take a wide range. The frame here shown consists of a background of card board, upon which the scales of pine cones and acorns are tastefully arranged, and fastened securely by fine, stout thread. After all the parts are put in place, a coat of shellac varnish may be given which will greatly improve the appearance. The thermometer is secured in its position in the frame by means of fine wires which are made fast upon the back side of the frame. A thermometer thus framed is much less liable to be blown down by a sudden gust of wind or knocked from its fastening by accident, or through carelessness.

**Learning to Sew.**—To be handy with the needle, is one of the sterling accomplishments of every educated woman. To be able to take the "stitch in time," is worth all the time and trouble that are required to learn the art. Like walking, reading, and the many other things which we come to do without special thought, the learning to sew is a slow

process, and should be begun while the child is still quite young. The girl should not only have the use of the thread, needles, and patchwork, but be instructed how to take the stitches, turn the corners, and do the various things connected with needle-work. We are not excluding the boys in our remarks, because they need to learn to thread a needle, and do general sewing. Men are many times so situated, that they must depend upon themselves for their necessary sewing. Even if it is an age of sewing machines, it is best that all children should learn to use the simple, common old-fashioned kind, which can never be wholly superseded. The amusement and occupation that sewing furnishes little folks, afford sufficient reason why all mothers should see that their girls, and boys too, learn to sew—but the very practical use of the needle in after life, is the principal thing after all.

BY FAITH ROCHESTER.

#### Some Things to Consider in Moving.

The 1st of May is general moving time in many towns and cities; and the residents in these, in seeking a new dwelling, find that there are many things which should be taken into account. If you have a family of little children, you must consider the moral influence of the neighborhood, and you will desire to shun the vicinity of liquor saloons or disorderly houses. You will hardly like to take your little ones into a neighborhood where the children are called a "hard set." Pure air is one great essential. Do not be satisfied with the general "lay of the land," but cast an eye on your near neighbor's back yard, after duly inspecting the one you propose to make your own. Is your well so situated that the water is likely to be pure? Is there a chance for keeping everything neat and clean about your own premises? Are there stables, pig-stys, or other probable nuisances on your neighbor's premises so situated that they are likely to poison the atmosphere daily breathed in your own house? A friend of mine secured a pleasant house, in a healthy situation, with a charming view of lake and city from the west windows. Not until he was settled in the new house did he observe that the low chimneys of a house close by obliged him to keep the pleasant west windows closed in order to avoid the smoke almost always blown from the west against his house. This annoyed him so that he gave up the house and sought another, for the view from his west window and the pleasant breeze from the lake were the chief attractions of the place. A lady of my acquaintance rented a small house for herself and children, and supposed it would be an easy matter to get settled in the new home. But she neglected to explore the cellar, which had no outside door, until she had cleaned and occupied the first and second stories. Then she found a task indeed, and an explanation of the sickening odor that hung about the place in spite of all previous cleaning. Several barrels of vegetables, mostly potatoes, had been frozen in the cellar during the previous hard winter, and had never been removed, though it was now mid-summer.

A house-keeper wants a house where the work may be done with least inconvenience. A business man wants a place convenient to his work. For the children there must be nearness to some good school. The mother wants a safe place for the little ones to play out of doors. The one who does the housework inquires anxiously if there is a good cistern or some plentiful supply of soft water.

#### Oiled Floors.

All who have tried them, so far as I have learned, cordially recommend oiled floors for kitchens, or other rooms where carpets are not used. These are preferred to painted floors, because the color does not wear away and leave bare places. Some use Burnt Umber with the oil, and so give a darker color to the wood. Others use oil alone. Boiled Linseed Oil is used, and it is applied hot, with a paint brush, a scrubbing brush, or even with a cloth. Rub it in well, and henceforth have no fear of grease spots on the floor. Farewell to all scrubbing hereafter. The oiled floor needs only washing (or mop-

ping) with clear, warm water. Of course soap would only tend to undo the work you have done in oiling. The hot oil should be re-applied occasionally. It comes in well as a part of each year's house cleaning.

#### Rag Carpets.

My new one—new two years ago—is almost worn out now. And yet, though this one has not done very good service, I think more of rag carpets than I used to. It is not because they are especially fashionable, for I have seen only one rag carpet besides mine since I put it upon the floor. That other one, in the sitting-room of a near neighbor, has since given place to a cotton carpet of gay colors and pattern, costing half a dollar a yard. When I "run in" to see my neighbors, I usually sit with my feet upon an Ingrain or a Brussels carpet. It is very pleasant, and I admire the neat carpet and the flowering plants, and all the dainty trifles on shelves and brackets. But when I go home and find my "hit-or-miss" rag carpet strewn with the little girls' dolly work, and the little boys' whittlings, and the baby's crumbs and playthings, I am glad it is only a rag carpet, and that I am not obliged to worry about the injury which would daily happen to a nice carpet where five children spend a good part of their waking hours. Besides, I think it is more "Eastlakey" than the very gay carpets of some of my neighbors! Anyhow, it harmonizes better with my very plain sitting-room furniture than good Ingrain or Brussels carpeting would. I like nice things, and if ever Fortune gives them to me, I shall be thankful I hope, as I am now for babies and for the companionship of childhood, and for the experience of a mother. I believe I will make one more rag carpet, at least. I think it will be "hit-or-miss," instead of striped, and I think I will put it down as I did this, without sewing the breadths, but simply lapping them, one a few inches over the next, stretching each one well, and tacking them very little except at the ends. It is easy then to take up and shake or beat the carpet and put it down again, so that the worn places may be less exposed. It is easy to wash out the most soiled portions. I will have a stronger warp next time, and think I will have it in two colors, so that there will be stripes running lengthwise of the breadths. I will be particular in cutting and tearing the rags to have them so that they will be even-sized threads in the filling, for I have never liked to see the places in this old carpet where thick woollen rags have sometimes joined on to finer cotton strings, making the texture of the carpet uneven, and causing it to wear out more easily. The little girls must sew them neatly, so as not to give a bunchy look when woven. I think I will have the rags divided into three kinds for sewing—a basket of dark rags, one of light, and one of gay colors. The first may include the black and dark-browns and grays. The second will contain the light nondescript grays, browns, and old calico stuff; the third, anything at all bright. The one who sews can go round and round with these three lots, and so make a tolerably even "hit-or-miss." I am not sure that this will pay, but I am sure that I know of no carpeting for 50 cts. a yard that will do so good service as a good rag carpet made in the above mentioned way.

#### Trading With Rag-Buying Peddlers.

If the "rag man" paid as well for old rags as formerly, or if our old clothing sold for near the price which the second-hand dealers charge for it when they sell it, it would not pay most of us to make rag carpets. I was so disgusted with my last sale to a rag-buying tin-peddler, that I have been less saving of old rags since. I turned off so many things—a large bag of rags, a long piece of old hemp carpet, a cracked iron tea-kettle, and a few other trifles—that I expected to get, at least, a dollar's worth of new tinware. I got only two pint basins! And I meant to mend that old tea-kettle, but the sudden hope that I might buy a new one with the old things I was selling, led me to part with it. I wanted to try a recipe for mending cracked ironware, which I had been saving for some time, and if it proved as efficacious as it promised, I was going to report the case for the benefit of the readers of my "Home Topics." When I told my good next neighbor of my sale, she

said I did no worse than she did. She sold an old pair of pantaloons to the peddler for twenty cents—not a large sum for them—and learned afterwards that a new seventy-five cent knife was in one of the pockets, and went of course with the garment.

### Out-Door Games.—Lawn Tennis.

The desirability of exercise in the open air need not be argued; all sensible persons admit it at once, but when they come to the question of "ways and means," the manner of securing this exercise, there will be found great differences of opinion. Some over-practical persons will say, "my girls can get all the exercise they need in making the beds

tion of the "Tennis-Court," as the game required a space 112 by 40 feet, and surrounded by a wall 20 feet high on the sides and 30 feet at the ends. It was originally played by striking the ball with the hand, which was protected by a strong glove. In the 15th century, the "racket" was introduced, a strong and peculiarly-shaped battledore for striking the ball instead of using the hand. This caused a change in the name of the game, which was formerly called *paume*, the ball being struck with the palm of the hand; but the player with the racket was cautioned by the cry of: *tenez* (pronounced *ten-nay*) which means "hold" or "hold hard," as it required a firm hand, and in time the word became adopted as the name of the game. But the

game has been modernized and improved; it is now played upon the open lawn, which is not only vastly more cheerful, but brings the game within the reach of all who have a grass plot of moderate size. The space for the game is still called a court; it is marked out, usually 27 by 78 feet, though the dimensions vary. Across the middle is a net which is stretched between 2 posts; this is 4½ feet high at the posts and 3 feet in the center. The space each side of the net is divided

Fig. 1.—A BOX OF TENNIS GOODS.

and sweeping the rooms," or that "my boys get exercise enough behind the plow during the day." Such persons fail to appreciate the difference between work and beneficial exercise; those very girls will be as wide awake for a turn at croquet or the boys for a game of ball as if they had been idle all day. Useful exercise, in the way of recreation, is something more than a mere mechanical movement of the muscles. Exercise as such, undertaken as a recreation, only brings its best results when it occupies both the mind and the body, and when the movements of the body are directed to the accomplishment of some end that the mind has planned. The best recreation is that which is directed to the overcoming of some obstacle, or to excelling some rival. Open air exercise to be most beneficial

into four parts, each having their names; the balls are about 2½ inches in diameter, of rubber, and variously covered. The Racquettes, or bats, are regarded as a most important part of the outfit, and good players are very particular in their choice of them. They look something like a highly civilized, long-heeled and rather one-sided snow-shoe, as, like that, they consist of a frame-work strung with cat-gut; some styles are of different colored woods and highly polished. These are the materials required for the game; as to the game itself we do not propose to describe it further than to say that, like all such games, there is an attempt of one side to do something with the ball, and it is the object of the other side to prevent its being done. It is of course governed by various laws in the observance and violation of which the gains or losses are made. The great strength the old game required of the player, in striking the ball with the hand, gives place to skill and dexterity in the modern player, who finds the wielding of the racquette a

Fig. 2.—A RACQUETTE.

should be social, it ought to allow both sexes to participate, it should be competitive, and unlike any form of work. Croquet acquired its popularity, because it met all the requirements of an out-door recreation. The same may be said of Archery, though it has not become equally popular. But we naturally incline to variety, even in our amusements, and any out-door game to be popular must have all the essentials of croquet. It must be social, easily learned. There must be a demand for skill which calls for the exercise of both mind and body, it must include competition or rivalry, and the outfit and appliances must not be too expensive. Lawn Tennis is all these, and its popularity in England, though the game has been slow in crossing the Atlantic, is but the prelude to that which awaits it in this country. Tennis proper, is one of the games that have a history; it became popular in Europe in the 15th century, and is said to closely resemble, if it be not actually derived from, a game of the ancient Greeks and Romans. In historical works and in fiction in which the scene dates back a few centuries, we find men

healthful exercise, quite sufficient for the development of strength of body, and ease and grace of movement. Lawn Tennis bids fair to have a long career and not less popular than that of Croquet.

### Household Notes and Queries.

**THE CLOTHES LINE.**—By many persons the clothes line is looked upon as a general necessity but a very common nuisance—and in many cases the judgment is a just one. The clothes line is proverbially in the way, especially if an axe is to be used in splitting wood in the back yard. This ought not to be. The line should be taken down so soon as the clothes are removed. Of the many devices for doing this the oldest seems to be the best: the simple method of winding it over the elbow and hand, and securing the coil with the end of the rope. The various patent folding clothes bows have the advantage of closing up into a small space when not in use, and some allow of the frame and line, to be readily removed to the house. What-

ever the method of suspending the line, let it be as much out of the passage ways as possible.

**A HOME MADE TABLE.**—The table which is shown in the accompanying engraving, is one that can be constructed in the farm work-shop during rainy days, and thus afford pleasant occupation for the older boys. A light table that can be easily moved, is one that every sitting room should pos-

A HANDY SITTING-ROOM TABLE.

sess—one that can be drawn up to the fire, in front of the window, and yet one that is not easily overturned. The kind of wood used, and the degree of ornamentation, will depend upon the lumber at hand, the skill of the person, and the time at his disposal. Light wood, like pine, or white wood, serves best for the top, with its narrow edging, while a stronger wood, like ash, will be best for the legs. The whole table may be made of inch stuff, excepting the edging to the top, which should be thinner. A table thus constructed, and afterwards covered with a close fitting cloth will be a very handy addition to the sitting room.

**SHOE-BLACKING STANDS.**—It is not expected that very much of a shine is to be kept on the "every day" farm boots, but those for Sunday and other special occasions, should have a polish, because it adds so much to the neatness of the person at very little cost. A box of blacking and a brush, with a few minutes now and then, are all the necessities; but the great trouble is often in finding these three elements: brush, blacking, and time all together. Too frequently the blacking and brush are put up in some out-of-the-way place, and often un-

A HOME-MADE BLACKING-STAND.

duly separated, so that it takes too much time to find them, and if found, the brush may be dusty and dirty and the blacking spoiled. All trouble of this kind may be saved by having a small Blacking Stand like the one shown in the engraving, in which the "tools" may be safely kept, and are then always at hand. A thing is handy only when it is at hand, and in little matters like the one in question, this is the all important point. This stand serves a double purpose: as a place to keep the brush and blacking, and when the cover is turned back, a rest for the foot while the boot or shoe is being polished. This is far better than using a chair, both in its being more handy and saving the latter from being marred. The older boys, and the young men especially, should provide themselves with such stands, either by making them, or by purchase, as they can be obtained at the furniture stores in a great variety of shapes, sizes, and styles, some of which make very nice stools, and can be used as a "step" for reaching high objects.

## BOYS &amp; GIRLS' COLUMNS.

## The Doctor's Talks.

Several have written about kites; one boy wishes to know how to make such kites as are sold in the stores, and another asks something about kite-flying. In the flying of a kite we have an excellent illustration of an action of force that I have not referred to in these Talks, but which may well come in here. But before we can fly our kite we must make it. Some boys get a great reputation among other boys as kite-makers; their kites always go up, and behave themselves when they get up. I don't know how it is now-a-days, but such boys used to get a great many pennies from other boys, with more money and less skill. As I recollect about the kites of the famous makers of my boy days, they were always

## LIGHT AND STRONG,

and I think that there was something about the "belly-band" that they prided themselves upon knowing. The two forms of kite the most common are the "Bow Kite," and the "Three Stick" or "Six-Sided" Kite. By far

Fig. 1.

the handsomest kite in my opinion is the Bow Kite (fig. 1), and I do not think it is altogether because it was the only kind we had when I used to fly kites. To make a kite of this kind that will fly well, requires more skill than the other. All the material should be as light and as strong as possible. For the stick, dry and straight-grained pine; for the bow, a piece of a barrel hoop is generally used, whittled down narrow, but the best is a piece of rattan, which for a small kite may be split. The cord should be cotton or linen, as it is much lighter than hemp of the same size. For paper, boys usually take

newspapers, and as there is much difference in the kind of paper these are printed on, you will need to pick out the strongest. Then with some common flour paste, some strong linen thread, a knife and scissors, you are ready to go to work. You may make a kite entirely by guess and have it fly well, but boys should always learn

## TO WORK FROM MEASURE,

when in building a kite, a sled, or a bird house. It is so long ago that I have forgotten the proportions we found best, but I found some in an English book. I made a drawing on a large piece of paper according to the measures, and as the kite looks right, I venture to give them. Length of stick, 40 inches; bow, 30 inches. Make a notch near each end of the bow, and then find the exact center of the bow, by balancing it on the edge of your knife, and mark the place with a small notch; 4 inches from the top of the stick make a notch to admit the bow. As to the stick, it should be carefully worked down by whittling as small as may be, and yet be strong enough, and here you must use your judgment; point the top, and make a notch to let in the bow a short distance, but not enough to weaken it, put the bow in place, and bind it fast with a few turns of thread. Then tie a cord to one end of the bow, carry the cord once around the stick, and then to the other end of the bow, bring the bow into shape; then fasten the cord tight; the distance from each end of the bow to the stick should be 10 inches, and the string should cross the stick just 10 inches below the point where the bow is fastened to it. Now pass the string from one end of the bow down to the bottom of the stick, through a deep notch, made there for it, then up to the other end of the bow, make it fast, and the frame is finished. To put on the paper, lay the paper on a table, and if one piece is not enough, join two by pasting them together with a lap of about half an inch. Cut the paper an inch larger every way than the frame. Before pasting, cover the table with newspapers, so as not to soil it with paste. At the ends of the bow, and at several places between the two ends, cut notches through that part of the paper that is to be turned over, so that it can be pasted without any bad wrinkles. Apply paste to the inch margin, and turn it over neatly, and let the paste get thoroughly dry before handling the kite. Some make a point to the kite; if this is wanted, measure four inches upon the bow, each side of the stick, and cut a small notch at each place, and make a notch at the top of the stick. Tie a piece of cord at one of the notches on the bow, pass it over the end of the stick to the other notch on the bow, and tie fast; this will make a spear-like point when covered with paper. Your kite is now ready, except two very important things, namely, the

## BELLY-BAND AND THE TAIL.

We may call that part of the kite upon which the stick does not show, the front side. You need to make a small hole through the paper from the front, on each side of the stick 10 inches from the top of the stick, and two more holes 10 inches from the bottom; the cord is to be passed through the upper holes with a turn around the stick, and tied very firmly—then through those below, leaving the band quite slack. The string of the kite is to be tied to this. The cord for the tail is tied in a similar manner to the stick at the bottom. The tail is made variously; sometimes one heavy paper tassel is fastened at the bottom; sometimes a long strip of cloth is used, but I don't think anything looks so well when the kite is up as the old fashioned bob-tail; pieces of paper, about 3 inches square, are folded up and fastened upon a string by a loop in it that every boy knows how to make. The tail may be very long (sometimes 15 times as long as the kite) and light, or shorter and heavier; the size is best learned by practice. Some make wings to the kite; these are merely paper tassels, attached at each corner of the bow, and are of very little account.

## THE THREE-STICK, OR SIX-SIDED KITE,

Is, I find, thought by some of the youngsters of the present day, to be much the best kind of kite, but to those brought up on the other kind it looks like a very clumsy

Fig. 2.

affair; it is, I think, the kind that one boy refers to as the kite "sold in the stores." These kites, as I have seen them, are made of three light sticks; these have notches at each end and are tied together, as in figure 2. After the tying is securely done, the cord is passed from the end of one stick to that of the next, and so on all around, and made fast at each notch. This frame is then covered with paper, as I described for the other. When dried,

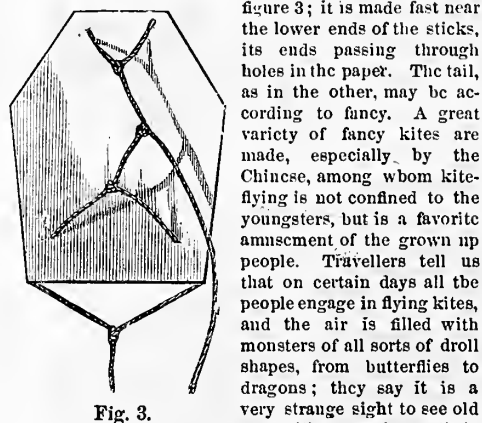

Fig. 3.

the belly-band is to be arranged, and this is quite different from the other, as seen in figure 3. Holes are made through the paper and cord passed through and tied around two of the sticks in such a manner as to make a loop above, and a broader one below, a cord connecting these two loops forms the belly-band, to which the kite-string is to be fastened. A similar loop must be made to which to tie the tail, as you see at the bottom of figure 3; it is made fast near the lower ends of the sticks, its ends passing through holes in the paper. The tail, as in the other, may be according to fancy. A great variety of fancy kites are made, especially by the Chinese, among whom kite-flying is not confined to the youngsters, but is a favorite amusement of the grown up people. Travellers tell us that on certain days all the people engage in flying kites, and the air is filled with monsters of all sorts of droll shapes, from butterflies to dragons; they say it is a very strange sight to see old men with spectacles on their noses, flying kites with as much earnestness as if their happiness depended on it. Sometimes these strange

## CHINESE KITES

are imported; but they are usually of the smaller kinds and shaped like butterflies or birds; those that I have seen have the frame work of split bamboo or rattan, and covered with a paper very unlike anything we have, and I think that some are covered with a very thin cloth. They are ornamented by painted designs, the most common being large eyes. They probably put eyes on their kites for the same reason that they put them on their junks, as their clumsy vessels are called. These always have at the bow a pair of enormous staring painted eyes. Upon being asked why they made eyes upon the junks the reply was: "No hab eyes, how can see?"

## IN FLYING THE KITE,

you need string, in fact, as the boys say—"no end of string," and here as in everything else about the kites "light and strong," will apply to the string. It is not easy to get a kite up in a poor wind; but if there is a good breeze and you have a good kite it will go without trouble. All of you who have raised a kite know that the best way is to let another boy hold it, while you, having let out a good length of string, start and run against the wind, when instead of following along after you the kite will go up. Why it should rise, and if the

wind blows, and you give it string it should keep going up, is a matter we must leave until another time; it has taken us too long to make our kite for us to fly it now. But in kite-flying let me give the boys—and girls too—

## ONE SERIOUS CAUTION.

Never fly a kite in the road. Nothing so frightens horses as to see a strange object above them; I have seen horses that would not mind the noisiest rail-road train, made perfectly frantic by a glimpse of a kite in the air at no great height. There is nothing that will so thoroughly frighten a horse as a kite. This should be borne in mind when enjoying the sport, for it would make you very unhappy should your pleasure be the indirect cause of a serious injury to some one, as might be the case.

**Picture Puzzle.**—This is a rather strange looking shrub, and the animal—fox or woodchuck we will suppose—at the base appears to be in trouble, one of his paws having found its way into a steel trap. There is

still more to the picture, which, no doubt, all will be able to see. Much of the pleasure, to us, connected with this picture, is that it was designed by a little boy, and the sketch was sent to us to see "what we thought of it." How do you like the ingenious picture? Does it catch you?

## Our Puzzle-Box.

## CHARADES.

1. My first is a cover just twisted around.  
My next is a fair lady's name.  
My whole a most awkward position is found.  
May you never be placed in the same.
2. My first names a certain class of individuals; my second is an exclamation; my third is a kind of dwelling, and my whole is a fish.
3. My first in winter oft you see.  
My next near you is sure to be.  
My whole is found on the shore of the sea.

## NUMERICAL ENIGMAS.

1. I am composed of 22 letters:  
My 9, 19, 8, 21, 12, is a piece; so also is  
My 13, 20, 6.  
My 1, 18, 19, 22, is something sacred.  
My 15, 17, 7, is generally despised.  
My 5, 10, 18, 3, 14, is much used in building.  
My 11, 4, 19, 12, 3, is a girl's name.  
My 16, 2, 17, is a boy's plaything.  
My whole is a well-known proverb.
2. I am composed of 32 letters:  
My 4, 14, 31, 28, 8, 24, 3, 9, is an Egyptian vegetable.  
My 13, 30, 7, 23, 12, 9, 30, 2, was a queen of Persia.  
My 17, 15, 30, 15, 22, 6, 23, 21, was a prisoner with Paul at Rome.  
My 23, 10, 3, 32, 16, 11, 21, 1, was a precious stone in the Highpriest's breastplate.  
My 26, 14, 23, 15, 27, 25, 30, 12, was a city of Macedonia.  
My 29, 5, 18, 10, 29, 27, 5, 19, is a bitter herb.  
My whole is a verse of Psalms.

## DECAPITATION.

- (1) Entire I'm found on many a farm,  
And when I've lost my head,
- (2) I'm useful found my whole to cook,  
And turn it into bread.
- (3) Once more I must beheaded be,  
Would you enjoy your food,  
Unless I helped you with the bread  
'Twould do you little good.

F. J. D.

## CROSS-WORD.

My first is seen in autumn, but never in the fall;  
My next is seen in cricket, but not in bat or ball;  
My third is in the primrose, but not in hedge or bower;  
My fourth is in the fortress, but not in wall or tower;  
My fifth is in the forest, but not in bush or tree;  
My sixth is found in laughter, but not in song or glee;  
My seventh is found in butter, but not in cream or milk;  
My eighth is seen in muslin, but not in wool or silk;  
My ninth is found in herring, but not in all kinds of fish;  
My tenth is found in platter, but not in cup or dish;  
My whole is a misfortune,  
No matter how it came,  
Sometimes attributed to fate,  
Even though yourself to blame.

## A River Hunt.

When DeSoto discovered the Mississippi River, it is said he was almost beside himself with delight, and felt abundantly paid for all the time and trouble given to the search. It is hoped that a like feeling, though in a smaller degree, may fill those of our young readers that may now set out on a River Hunt. The "large streams of water flowing through the land" are brought much nearer together on our peculiar map than they are in nature, and again they do not have that resemblance to each other that the ordinary geography gives them. The first river which we will set out to find rises

in a lake in the western slope of the Rocky Mountains, and after flowing south some distance, forms a part of the boundary between a State and a Territory. It is full of remarkable bends, rapid throughout, and has cataracts in the mountain gorges. Its length is 1,200 miles. The tributaries are noted for the length of their names.—No. 2. After a winding course of about 1,500 miles it flows by a delta into the Atlantic Ocean. The delta is of great size, and the mouths are very numerous. The land drained by this river is 250,000 square miles, most of which is occupied by a vast woodless plain. There are two remarkable rapids in the stream in which the natives are often dashed to pieces in their attempts to pass them in canoes.—No. 3 has its source on the borders of the United States, and after flowing in a southerly direction, passes into a large Sound, and thus to the ocean. On its way it forms the boundary between two important States, and the valley through which it afterwards flows bears its name, and is noted for its fine farming land. The State is also of the same name.—No. 4 is a small river of only 135 miles, and a tributary to one that flows by the side of the largest island city in the world. This short river flows through one of the finest regions in this country. Its name comes from a tribe of Indians which once lived in its valley.—No. 5 begins at the foot of a great lake, and afterwards serves as a portion of the boundary of the United States. After a run of 750 miles, it expands into a gulf which bears the same name. If not the longest, this is one of the largest and most important rivers in the world. It is noted for its beauty, celebrated cities, and many islands. A trip down this stream is now frequently taken by pleasure seekers.—No. 6. This great river is, like many others, formed by the union of smaller ones. It flows through treeless plains, and in many places the banks of the river are very high and steep. Sometimes these gorges are 7,000 feet, or almost a mile in perpendicular height. The country along this river is noted for its relics and remains of races of people that lived many hundred years ago.—No. 7 is one of the smaller rivers, but it has a big name. Its course is south, and many of our boys and girls will have to go South to find it. This is no reason why it was put near the bottom of our map. It flows into a bay, and then the water passes into a gulf.—No. 8. This is a small river wholly within the borders of a single State, and empties its water into the ocean near a cape of the same name.—No. 9 is one of the main branches of one of the leading tributaries of the largest river in the new world. This is a very familiar river to those who live in a large city, noted for its iron foundries and the smoke that is constantly hovering over it.—No. 10. The leading river of a large lumber State. It receives a number of tributaries on its way to the bay of the same name, which is of Indian origin, as is the case with many American rivers.—No. 11 flows through a comparatively level country, and adds its waters to a great south-flowing stream. The country

A MAP OF SOME STRANGE LOOKING RIVERS.

readers: "What is that which runs and never flies—legless, wingless, with four eyes?" To go from one end of this mighty stream to the other—from the little clear lake up in the North to the great gulf in the South—all along through that great Valley, with all its fertile acres, which is the pride of our great land—would be a long and a pleasant journey; but having discovered—or at least made the discovery easy—we will leave the readers to decide the matter of further travel for themselves.

## Another of the 'Ologies.

Some one asks, "Why don't you have some more of those 'Ologies'?" There are a great many "Ologies," and most of them are too hard for boys and girls to understand. In February we selected *Pomology*, because we thought—yes! we knew, that fruit was a subject about which young people liked to hear. The study of the various kinds of strawberries, especially when they are ripe, is pleasant—to learn to distinguish in taste between the finest kinds of pears, peaches, and grapes, is both interesting and agreeable. For young folks, there is probably no 'ology that stands ahead of *Pomology*, but if we must talk about another 'ology, let us select *Zoology*. This word means a "telling about animals," and a person who can tell about animals—that is, can say a good deal concerning animals—is a *Zoologist*. "But why Zoologist?" you will ask. The "ology" part of the word you understand, the first part is also from the Greek, from *Zo-on* (in two syllables), the Greek word for an animal. A boy or girl that makes a study of animals may in time become a *Zoologist*. There are a number of men, and some women too, who spend most of their time in finding out all they can about various animals, and some of the animals they study are so small that they can not be seen without the use of the magnifying glass or microscope. "But what is an animal?" some one asks. That is a harder question to answer than you think for. All living things—all things that grow and

die—are either animals or plants—so the Naturalists say. Now, what is the difference between an animal and a plant? It is easy to see that a cow is not like a rose bush, or a mouse has not much in common with a maple tree—there are a great many differences between these; but when the *Zoologist* comes to study the little, minute forms of life, so small that he must use a microscope—so small that a drop of water could contain thousands of them—he says he can not tell the animal from the plant. But for our purpose an animal is a living being that can move around and has feeling; eats, drinks, and sleeps. How many animals are there on a farm? Some will guess five; others ten, and some will go as high as fifty.

### Fishing and Fishers.

There is something about fishing that is very attractive to youth. The very thought of pulling out a great fish—hand over hand—is enough to make a boy's heart go *thump!* and make him wish to leave his work, or his desk at school, and try his luck with a baited hook in the lake or the running stream. It has always been so, and it is not likely that the love for catching fish will ever die out. I remember as if it were yesterday the first time I ever caught a fish on a hook. It was a small lake perch, a very appropriate fish for a small lad to get on his hook. But it was not long before I added another to my string,

the rushing, roaring, hoisterous freshet-river of a few weeks ago—now so faint in its music and so lazy in its motion. The best pool has been found—it is not always the largest—and by the looks of things the boys have been at work for some time—*but still they come—I mean the fish, not the boys.* What a nice fish the largest boy in the front of the picture is taking from its watery home. How he enjoys the work of bringing him to the shore; but on the other hand, what a new world is suddenly opened to the eyes of the astonished fish, suspended there in mid-air above the pond! It will be observed that the fisherman on the left of the pond does not take any delight in the capture of this fish. The truth is, he has had

THE BOYS' MAY HOLIDAY AT THE POND.

Suppose we should count them, using the number of legs as a guide. How many with four legs?—All will mention the horse, cow, pig, sheep, and dog. That makes five four-legged animals. But there are the mice and rats that most barns contain; the woodchuck is down by the woods, and near him there may be the squirrel, the weasel, the coon, and that had smelling fellow, the skunk. If we look closely, there are other four-legged animals to be found, but let us go on. Are there any animals with three legs? Not unless one with four legs has lost one in a trap or some other way. Two-legged animals are numerous, and some of them very important—one does not have to go very far from himself to find one of these. There are the birds, and the chickens, geese, ducks, turkeys, etc., all of which are birds.—Are there any one-legged animals? The only one-legged thing common on farms is the milking stool, but that not being an animal, can not be counted here. We shall have to give up our search for animals with only one leg. Here we come to a thought. Are legs in pairs in all animals? We have found them thus far in twos and fours. Are there any animals on the farm with six legs? Just look at the insects; the flies, beetles, bugs, butterflies, etc., of which there are hundreds of kinds on every farm—they all have six legs. If spiders are examined it will be found that they have four pairs of legs. But we can not go all the way from the two-legged animals to the "thousand-legged worms," and see if they are all in pairs, but must take the word of those who have looked over the whole list—the *Zoologists* tell us legs are always in pairs.

If we should take the eyes and ears, the teeth and brains, and all the other parts, and find out about them in the thousands of kinds of animals, we should then become *Zoologists*. The subject of *Zoology* is a very large one, but no children have the chance of learning about all sorts of animals like farmer's boys and girls. Some of our best *Zoologists* have lived upon farms while young. We wish all our many young readers would interest themselves to study animals, and in time become *Zoologists*, so far as having a knowledge of common things about common animals will make them such.

after which fortune did not seem to favor me, try as I best could, and no more were taken. Before this, I had done a little fishing on a very small scale in the way of hand-catching among the stones in a little stream that flowed through the farm. With my shoes and stockings on the bank, and my trousers rolled tightly up over my knees, I would wade along the stream until some frightened minnow was seen to dart under a flat stone, when with hands extended around the opening I would corner the poor fellow—provided he did not get out some back way or pass like a flash between my feet or fingers. Sometimes I have succeeded in catching much more than I bargained for, when some old crab grasped my toes or fingers as they extended into its secluded hiding place.—But the little slippery fish did not always get away, and in the course of an hour or so I sometimes had a number of them in my little tin pail. Frequently I made a small pond for my fish and put them in it; but better still—for me at least—was the watering trough at the well near the barn, into which I put my minnows, and with stones and pieces of brick made them a place to run under to get in the shade and out of the sight of the horses, and I may add, away from the eyes of a person who came with the horses. But it did not matter much what I did with my little fish, something would happen to them, and it was frequently found necessary to get a new supply from the brook to keep up the stock. In the course of a few years I outgrew this pail and finger-fishing, and with a line made of strong thread—shoe thread—a hook which had once served as a pin, and a few worms from the chip dirt or from under stumps, overturned many times a year for bait, I would go with the neighboring boys for an afternoon of fishing in the pools and deep places in the hedges, and at the foot of large trees in the same brook from which the minnows were taken when I was too small to handle a line, but too big to stay at home. The artist has given us a view of one of these fishing days—one of those Saturday afternoons in May when fishing is so much enjoyed, because it comes so near to doing nothing—a kind of occupation which the warm, sultry days, so frequent at this season, render doubly inviting.

The stream is not a large one, not to be compared with

"bad luck," and it begins to tell upon his face, which is growing long as the sun is getting low. He has either had a bad hook, poor bait, unfavorable light, a shallow place, put his line too deep, or held his line wrong in some way, so that the fish have gone to more inviting hooks. It is sometimes hard to see just why the boy at your side will catch the fish right away from your hook. The little lucky fellow on the opposite side of the pool has a fine string of fish, and is evidently telling something to that effect to his unfortunate friend. He appears to be so well satisfied with his afternoon's work that he will soon go home and exhibit his catch to the older members of the family—and perhaps find out how the fish taste, when nicely cooked, before he goes to bed. The dog, though only a "looker on," evidently "sees most of the game," and is as much pleased when a good fish is caught as any one else in the fishing party. From the way the nearest cow pricks up her head and ears, there must be some shouting being done by the boys—over the capture of the biggest fish of the day. But the boy must look out or it may get away and *float* into the pond again, as one is seen to be doing, to a boy's dissatisfaction. Many fishermen believe that when a fish thus regains the water, and is in the society of his uncaught friends, he communicates his experience to them, and cautions all the rest against taking any tempting worm or fly that may be presented. From that hour fishing is dull work. "They won't bite." So the story goes. That there is a fish-sympathy, though "cold-blooded" in its nature, is not unreasonable to believe.

I can not linger longer over this scene of my boyhood pleasure; and the boys must soon go too, and drive up the cows and see to their other chores; but as a last word, while they are trying for their final catch, the "last but not least"—the "just one more"—let me say that there is much fishing which they will find through life, though it may go by other names—it may be a hook well baited and thrown into the busy whirlpool of business—for money, or into society—for friends, station, honor. In this fishing there may be some "luck," but in the long run it is the patient, untrifling, upright, honest fisherman that goes to his rest in peace.

UNCLE HAL.

### Results of Vivisection.

*Interesting Experiments—Prof. Mott shows how People are Taking Poison in their Daily Food—A Prolific Source of Dyspepsia Scientifically Demonstrated.*

*From the New York Tribune.*

A series of highly interesting experiments with dogs has been lately made by Prof. Mott, and in the *Scientific American* of Feb. 7 a detailed account is given. The disclosures are so unpleasant and startling, coming home, as they do, to every one, that we believe they should be given the greatest publicity. The effort Dr. Mott is making to purify our articles of kitchen use should receive the support of every thinking man and woman. There has been too much indifference of this subject—an indifference that has resulted in Americans earning the title of "a race of dyspeptics." Poison year after year is introduced into the stomach with a criminal disregard to consequences that is appalling. If every purveyor of domestic supplies will carefully consider the result of Dr. Mott's experiments, as detailed in the *Scientific American*, one of the greatest, if not the greatest, of these evils will be corrected.

Dr. Mott says: "The introduction of alum in flour, for various purposes, has been a trick of the baker for the past 100 years. Fortunately for society, its introduction is limited now to a few unscrupulous bakers. In England, France and Germany it is an offense punishable by fine and imprisonment to use alum in any connection with articles of food. It should be so in America."

The Royal Baking Powder Company, of this City, a long-established corporation, celebrated for the absolute purity of their goods, some time ago commenced a vigorous warfare against many of their competitors who were indulging in hurtful adulteration. The contest excited great interest in scientific circles, in which Prof. Angell, Dr. Mott, and other leading lights took a very prominent part. The experiments of Dr. Mott are a result of this discussion, and go to prove conclusively that the most dangerous adulteration that a community has to guard against is alum in baking powder. In his paper, the Doctor says: "It was with difficulty I found a suitable place to conduct the experiments so that the animals would not disturb the neighborhood; but, through the courtesy of the Commissioners of the Dock Department, I secured a shed on their premises, foot of Sixteenth-street and East River. This shed I had completely remodeled into a snail house, having the dimensions of about 16x14x12 feet. Sixteen stalls were made inside, having the dimensions of 3x2x2 feet. The bottom of each compartment was covered with straw, making a pleasant bed for the dogs. I then secured 16 dogs from the Pound, which were all carefully examined to see if they were in a perfect state of health. None but the strong, healthy dogs were selected. The breed, age, food, color, and weight of every dog was carefully noted. Each dog was then confined to a stall and securely chained, and they all received a number, from 1 to 16. I commenced my experiments on the 9th of September, and finished Dec. 3. My assistant was with the dogs from morning until night, and never left the animals without first securely bolting and locking the dog-house. No stranger was allowed to enter the house unaccompanied either by myself or my assistant, and the dogs never received a mouthful of food or anything else from any one except from my assistant or myself. I will now detail the result of my experiments: "Dog No. 1—Breed of dog, coach. Age, 1 year. Health, perfect. Food, bread and crackers. Color, spotted black and white. Weight, 35 pounds.

"To this dog, on the morning of the 9th September, was given eight biscuits at 8:10 o'clock. The biscuit were made by myself as follows: One quart sifted flour, 20 teaspoons alum baking powder, 2 cups water, 1 tablespoon butter, 22 biscuits made, weighing 27 ounces; time of baking, 20 minutes.

"At 11:30, just three hours and twenty minutes, the dog was taken very sick, vomiting profusely; his vim and brightness of eye had departed, and he trembled considerably in his limbs."

Experiments were then made upon three dogs with biscuits containing only 10 teaspoons of alum baking powder. The result indicated that some animals are more liable to yield to the effects of poisonous substances than others are. When, on the other hand, three other dogs were fed with biscuits made with pure cream of tartar baking powder, no ill effects were experienced. The ate and ate with an evident relish, day after day, and even whined for more.

It was next necessary to discover what effect alum has on the solvent power of the gastric juice. In order to obtain some pure gastric juice, a curious device was resorted to. Dr. Mott sent several dogs to Prof. Arnold, Medical Department of the University of New York, who inserted a small metallic tube directly through the skin and into the stomach of each one of them, when the dogs were in a perfectly healthy condition. Prof. Arnold sent to Dr. Mott some gastric juice, which was produced by tickling the lining of the stomach of the dogs with a

feather or glass rod, which caused the gastric juice to flow out of the tube into a receptacle placed underneath the dog to receive it.

Dr. Mott, aided by Prof. Schedler, then began some experiments with the four samples of gastric juice, which he had received from Prof. Arnold, to discover the effect of the gastric juice in which alum has been dissolved upon fibrine, a white, very easily digested substance having a basis of coagulated blood. The fibrine was imperfectly digested, and the experiments were very important, as showing that alum can check the digestion of so easily digested a substance as fibrine. They indicate, therefore, how dangerous it is to introduce these two salts into our stomachs, if we do not wish to excite indigestion and dyspepsia. Further experiments showed that the digestive power of the gastric juice is entirely destroyed by alum, so far as its power of dissolving the more indigestible substances, like the boiled white of an egg, is concerned.

Dr. Mott then determined to learn whether alumina could be found in the various organs of the body if a dog was fed with hydrate of alumina. He found a considerable quantity of the stuff in the blood, liver, kidneys, and heart.

The Doctor goes on to describe the different symptoms exhibited by these dogs as they passed through almost every phase of animal agony until they were left in a complete state of physical prostration. To those especially interested in the details of this subject the article in the *Scientific American* supplement will give most complete information, and we will spare the sympathetic reader the account of the sufferings of these dumb brutes.

Dr. Mott's conclusions, after making these experiments, are of vital interest to every one who either makes or eats bread, and therefore concern all.

"These experiments," said he recently, while speaking before the American Chemical Society, "clearly demonstrate that the salts left in the biscuit when a cream of tartar baking powder is used are perfectly harmless, but when an alum baking powder is used are very dangerous, for in every case where dogs were fed on biscuits made with such powders the dogs were made very sick, causing them to vomit profusely; lose all energy, and show weakness in their limbs."

It is a clear and triumphant corroboration of the assertions of the Royal Baking Powder Company, and entitles them to the gratitude and support of the community they are endeavoring to protect. As they claim, and Dr. Mott has shown, bread made of alum is totally unfit for human or animal food. "Tis true, in the bread of domestic consumption there may not be as large a proportion of baking powders as was in the bread used by Dr. Mott, and that accounts for the fact that the symptoms in the reader are not so well defined as they were in the experiments in question. How many there are of our immediate friends suffering from this evil, scientific investigation will alone reveal; but many a lingering and suffering invalid, with no defined idea of his trouble, can easily trace it to its source by stopping the use of alum powders, substituting some brand like the Royal Baking Powder, whose manufacturers have a competent chemist in their exclusive employ, who rigidly analyzes every ingredient before its incorporation into their powder. The old cry of "honesty being the best policy" may be worn threadbare, but its truth will hold forever, and while adulterations and short weights abound, it is a pleasure to see at least one in the trade strenuously endeavoring to give full weights and pure goods.

The advertisement of "Aultman-Taylor" Threshing Machinery, which attracted such general attention among farmers and threshermen in our April number, will appear again in June.

Everywhere known and prized for Skill and fidelity in manufacture, Tasteful and excellent improvements, Elegant variety of designs, Yielding unrivaled tones.

# H.W. JOHNS' ASBESTOS Liquid Paints.

ARE STRICTLY FIRST-CLASS PURE LINSEED OIL PAINTS.

THE BEST IS THE CHEAPEST.

These are the purest, finest, richest and most durable paints ever made for structural purpose. They are prepared ready for the brush in sixteen newest shades and standard colors, suitable for the tasteful decoration of dwellings and all classes of buildings, inside and out, and for all purposes where a perfect protective coating is required, and, covering body and durability considered, they are twenty-five per cent cheaper than the best White Lead or any other kind of paint now in use.

Our Asbestos Liquid White has been adopted for interior and exterior work of the U. S. Capitol at Washington.

The Metropolitan Elevated R. R., of New York City, is painted with our paints.

ASBESTOS ROOF PAINT.—Brown, Red, Yellow, Gray, Slate, and Cream, for tin and shingle roofs, iron work, agricultural implements, fences, out-buildings, etc. We guarantee this to be a better article than has ever before been offered to the public for similar purposes.

## Flower Seeds Given Away TO EVERY YEARLY SUBSCRIBER TO The American Garden. A QUARTERLY ILLUSTRATED JOURNAL. ONLY 25 CTS. A YEAR. SAMPLE COPIES 10 CTS.

Devoted exclusively to the Gardening interests of America. Contains 12 large pages of closely printed matter, relating to Horticulture, Floriculture, the Lawn, Flower and Vegetable Garden in all their varied departments.

Edited by Dr. F. M. HEXAMER.

This popular magazine, heretofore published by Messrs. BEACH, SON & CO., will hereafter be published by the present proprietors in an entirely new dress, and will appear in January, April, July, and October of each year.

First number will be ready about April 30th.

### Flower Seeds for the Wild Garden.

Every yearly subscriber will receive in addition to the paper a packet of **Flower Seeds for the Wild Garden**, which contains a mixture of upwards of One Hundred varieties of Hardy Flower Seeds, sufficient for a square rod of ground, which will give a profusion of flowers during the entire season for several years in succession. Instructions for sowing and subsequent treatment of Flower Seeds, as well as for other plants for the Wild Garden, will be found in the April number of the *American Garden*.

B. K. BLISS & SONS, Publishers,  
No. 34 Barclay St., New York.

### IF YOU HAVE A GARDEN, YOU NEED

150 pages. Over 300 Illustrations, and a Beautifully Colored Plate of Pansies. Mailed for 10 cents.

**BLISS' ILLUSTRATED AMATEUR'S GUIDE TO THE FLOWER AND KITCHEN GARDEN** contains more practical information on gardening than many high-priced books. Our list comprises 2,000 varieties Flower Seeds, 1,000 varieties Bulbs and Plants, 500 varieties Vegetable Seeds, 500 varieties Potatoes, etc. 220 pages, over 600 illustrations, 2 double-page colored plates of flowers. Price: paper covers, 35 cents; bound in muslin, \$1.00.

**Illustrated Catalogue of Fruit and Ornamental Trees, New and Rare Plants, and Small Fruits**, mailed free to all applicants.

### Kenney's Early Amber Sugar Cane.

In this variety we have a plant of immense value to our country. When planted early in May, the seed almost invariably ripens, thus giving one the advantage of a double crop in one year, from one planting, some 20 or 25 bushels of seed, and 150 or more gallons of fine syrup per acre—900 lbs. sugar were produced from one acre in Minnesota. By mail, 40 cents per lb.; 3 lbs., \$1.25. Prices for larger quantities upon application.

B. K. BLISS & SONS, 34 Barclay St., N. Y. City. P. O. Box 4129.

My Annual Catalogue of Vegetable and Flower Seed for 1880 will be ready by January, and sent free to all who apply. I would invite attention to the superior character of the vegetable engravings, most of which were made from photographs of vegetables grown on my seed farms. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms. All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will recall the order gratis. As the original introducer of the Hubbard and Marblehead Squashes, the Marblehead Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed directly from the grower—fresh, true, and of the very best strain.

**NEW VEGETABLES A SPECIALTY.**

JAMES J. H. GREGORY, Marblehead, Mass.

### IT WILL PAY YOU

to get my Price List of Seeds and Plants—sent free. Best at lowest prices. My Plants are Stout, Healthy—just as if grown in the open ground—and very early. Canada Victor Tomato ripens by July 14th. LECTIONS, BY MAIL \$2.00

### A New Early Sweet Potato, EARLY GOLDEN.

This variety originated in Virginia a few years since, by an old cultivator of the Sweet Potato. It is a sport of the old **Early Red**, but said to be far superior to that variety in earliness, productiveness, color, and quality. Slips planted May 10th, produced tubers large enough for the market July 25th. On account of its early maturity it is believed to be better adapted for cultivation in the Northern States than any other variety. In shape they are somewhat shorter than the ordinary varieties, of a golden yellow color, cook very dry, and are of superior flavor. Another valuable consideration in favor of this variety is, that they will grow on quite ordinary soil with but a slight coat of manure, and yielded a large crop the past season upon land that would not grow above fifteen bushels of corn to the acre. In good soil they will produce many specimens weighing three to five pounds each. It is also an excellent keeper. From what we can learn from those who have tested this variety, we think it will prove the most valuable in cultivation.

Price of slips, with directions for planting, by mail, post-paid, 50 cents per dozen; \$1.25 for fifty; \$2.00 per hundred. By express at purchaser's expense, \$1.50 per hundred, \$12.50 per thousand.

B. K. BLISS & SONS, 34 Barclay St., N. Y.

### New Asparagus.

**Smalley's Early Defiance.**—Described by the originator as follows: "Sprouts of a pale green, of good size, very productive, and roots throwing off a great number of strong well developed shoots which can be cut two weeks earlier than any other variety, and will continue bearing through the entire season; very tender, and of delicious flavor. Its earliness makes it a very desirable variety. Packet, 25 cents; ounce, \$1; 1/2 lb., \$3.50; 1 lb., \$12. Roots, 1 year, 50 cents per dozen; \$3 per 100; 2 years, 75 cents per dozen; \$5 per 100.

**Pearl Millet.**—Clean Seed, 10 cts. oz., 25 cts. 1/2 lb., 60 cts. lb., 4 lbs. \$2.25. Seed in chaff, 50 cts. pt., 80 cts. qt., by mail, post-paid. Prices to the trade will be given on application.

**Prickly Comfrey Roots.**—25 cts. 1/2 lb., 50 cts. lb., by mail, with directions for culture.

**New Early Field Corn—Queen of the Prairie.**—The earliest variety of Field Corn in cultivation. It was planted, the last season, after the wheat crop had been harvested, and matured the crop perfectly. It was also planted on Long Island, July 4th, and fully matured the first of October. Selected ears, 25 cts.; 3 lbs., by mail, post-paid, \$1; shelled, \$1.25 per bushel; \$3.50 per bushel.

**Blunt's White Prolific Corn.**—Our seed of this variety is very extra, having yielded from 80 to 100 bushels per acre the past season. Price per bush., \$3.00; 1/2 bush., \$1.75; peck, \$1.00. By mail, pkt., 10 cents; 40 cents per lb.; 3 lbs., \$1.00; selected ears 25 cents.

**Chester Co. Mammoth or Golden Dent**, the largest, best, and one of the most profitable corns for the main crop. Bush., \$3.00; peck \$1.00; select ears, 75 cts. doz.; \$5.00 per hundred. By mail, 3 lbs., \$1.00—ears 25 cts. each.

**Golding Hop Roots.**—A new English variety, highly esteemed among the hop-growers of Kent and other portions of Great Britain. Large, productive, and of fine quality. A great improvement on any variety hitherto offered. We recommend this variety with the greatest confidence to all hop-growers. By mail, post-paid, each, 20 cents; dozen, \$2.40; hundred, \$10, at purchaser's expense.

### 3 New Potatoes.

**Pride of America, Matchless, Silver Skin.** For description, see April No. of *Agriculturist*.

**DEALERS IN PERUVIAN Guano**

EXCLUSIVELY,  
170 Front Street,  
New York.

**Soluble Pacific Guano.**

Having been appointed General Selling Agents of the Pacific Guano Company, whose works are at Wood's Holl, Massachusetts, and Charleston, South Carolina, we are now prepared to offer for sale this celebrated brand of Fertilizer. Made from pure hot-air dried phosphate rock, brought direct from the Company's mines at *Chisno's Island*, it is rich in **Bone Phosphate of Lime**, finely ground (a large proportion of which is immediately soluble), **Ammonia and Potash**, besides other ingredients valuable for plant-food. Although previously known principally in the Southern States, where the sales have steadily increased during the past twelve years from 745 tons to upwards of

**40,000 Tons in a Single Season,**

the successful results of its use in New York, New Hampshire and Vermont have fully justified us in offering the increased production of the Company's works at Wood's Holl to the *Farmers of New England*, for corn, wheat, grain, grass, and all garden vegetables and flowers.

We call attention to our pamphlets, showing the special analysis and directions for growing *Sugar Beets*, selected from tests made expressly for the *Pacific Guano Company* by the most celebrated chemists in this country and Europe.

For sale by our agents throughout the United States, and full particulars given by

**GLIDDEN & CURTIS,**  
General Selling Agents,  
BOSTON, MASS.

1880.

**Pennsylvania Lawn Mower,**

Surpassing all others and pronounced the best. Lightest, runs more easily, cuts longer grass, is more durable, requires less repair, cuts grass more smoothly, is less liable to obstruction, is of handsome appearance.

Penn. State Agricultural Society says, "It will, we believe, wear longer, do the work better with less labor than any other Mower. One of the peculiarities is that it will cut higher grass than any other Mower."

Every machine warranted. Address

Send for descriptive circular, price list, terms to agents, etc., to P. C. LEWIS, Catskill, N. Y.

## POTATO BUG. COTTON WORM. CANKER WORM. THE BEST INSECTICIDE EVER USED. London Purple. (Trade Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. If not obtainable, of nearest dealer, send direct to sole manufacturers, **HEMINGWAY'S LONDON PURPLE COMPANY (Limited)**, 60 Mark Lane, London, England. 90 Water Street, N. Y. P. O. address, Box 990.

A. R. WHITNEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have bid the Canker Worm a long farewell, and have done it with your LONDON PURPLE. We put in about three-fourths of one pound of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

## THE MONITOR SEED DRILL.

This is the most complete and positive Seed Drill ever invented. It is radically different from and superior to all others. It is the only machine which measures and drops the seed with a positive motion, and exactly the same amount at each foot or yard. It has been tested by 6 years' use in Massachusetts, and was awarded the highest prize at the "Centennial." The "MONITOR" has been thoroughly tested during the seasons of 1878 and 1879, and heartily endorsed as a

## HAWORTH'S WIRE CHECK ROWER.

Acknowledged by all farmers to be THE BEST AND ONLY PERFECTLY SUCCESSFUL Wire Check Rower. Will plant FIVE ACRES more a day than any other, as the Wire is not removed from the machine in planting the entire field. Eleven years' use has demonstrated the fact that the only successful way to use a rope or wire line is for the machine to transfer it into position to plant the next row. Do not buy a Wire Check Rower unless the line crosses the machine, as it will last twice as long as a wire run on one side, which must be dragged into position regardless of obstructions met as the planter crosses the field, and which causes friction, inaccurate checking, and breaking of the wire. In our Check Rower the elasticity of the wire and its large curve in passing over the machine, prevents a particle of bending or displacement in the wire, such as occurs in Check Rowers where the line is dragged into the pulley at an angle and high tension, and both bent and displaced as it enters the pulley. Dragging the line into position also causes canting, or lopping, of the planter, by which one row is planted too deep and the other too shallow. Our ROPE CHECK ROWERS are too well and favorably known to call for any extended notice. For full description of our WIRE CHECK ROWER and the three styles of ROPE CHECK ROWERS which we manufacture, write for a circular.

HAWORTH & SONS, Decatur, Ill.

## Hardy Perennial Plants

Are increasing in popularity, because they are Hardy, their roots living through the winter—and Perennial, appearing year after year in the same place. They include the most beautiful kinds that bloom all through the season, from earliest spring to latest fall. Send for free descriptive Catalogue of the largest collection in the Country—including Hardy Climbers, Flowering Shrubs, Lilies, Phloxes, Ferns, etc. Also choice native plants. **WOOLSON & CO.**, Box 180, Passaic, N. J.

**SHARPLESS**, 40 cts. per doz.; \$1.50 per 100, post-paid. Other kinds lower. **SNYDERS**, \$6 to \$10 per M. Lists free to all. **STONE LAKE NURSERY**, (Formerly Steele Bros.) La Porte, Ind.

## STRAWBERRY PLANTS.

All the new and standard kinds. Illustrated Catalogue sent free. **C. S. PRATT, AGR.**, North Reading, Mass.

## Salt is Necessary for Land, FRUIT TREES AND STOCK.

Lump or Mineral Salt is excellent for stock. A large quantity Agricultural and Dairy Salt on hand. Also Ferris' Land Invigorator and Crop Protector. Death to Hessian Fly and other pests. Use it and reap a golden harvest. **EDWIN FERRIS & CO.** Wholesale Salt and Fish Dealers, 183 and 185 Washington St., N. Y.

## TWO NEW POTATOES.

**Magnum Bonum** (not the English variety of same name), 518 Bushels grown in 60 days from one acre of ground without any manure whatever. \$100.00 in cash premiums to be paid in 1880 for the largest yield from one lb. of seed. Price by mail, prepaid, 1 lb. \$1.00, 3 lbs. \$2.00, 4 lbs. \$2.25. By frt. or ex. at purchaser's expense, ½ peck \$2.00, 1 pk. \$4.00, ½ bush. \$6.00, 1 bu. \$10.00, 1 bbl. \$20.00. **THE MAMMOTH PEARL.** For some unaccountable reason my adv. of The Mammoth Pearls failed to appear in *Apr. No. Am. Agr.* But I will now say that I will supply this King of Potatoes to the readers of this Journal, by mail, prepaid, 1 lb. 50 cts., 3 lbs. \$1.25, 4 lbs. \$1.50. By frt. or ex. charges paid by purchaser, ½ bu. \$1.50, 1 bu. \$2.50, 1 bbl. \$5.00, 5 bbls. \$4.00 each, 10 bbls. or more \$3.50 each. For fuller particulars of above, with testimonials, also Vegetable and Flower Seeds, etc., address **J. A. EVERITT**, P. O. Box 229, Watertown, Pa.

## SWEET POTATO

Plants, Early Peabody, Nansmond, Southern Queen, Jersey, Early Red, Bermuda, Brazilian. Mail, \$1 per 100, \$2 per 300. Exp. \$1 per 400, \$2 per 1,000, \$5 per 5,000, \$15 per 10,000. Write for circular. **W. W. KATHBONE**, Marietta, O.

**POTATOES.**—Northern Wis. Crown, Triumph, Ruby, Danmore, Davenport, Genesee Co. King, Little Giant, Superior, Success, and others. See 150c. peck, \$1.50 bushel. **DAVID GREENWAY**, Dartford, Wis.

## RELIABLE ONION SEED

From Selected Onions. Red, White, and Yellow Globe, post-paid, \$3.00 lb. Large Red Wethersfield, post-paid, \$2.50 lb. **E. B. JENNINGS**, Southport, Conn.

## LOUISVILLE GARDENS.

For Price Lists of Celery Plants, etc., send to S. RUPERT, Louisville, Stark Co., O.

## ONEONTA CLIPPER

This Plow contains the most remarkable improvements ever made in Swivel Plows. It is easy to handle, with Shifting Handles, which enables the operator to walk with both feet in the furrow. The Hook or Latch is operated by the foot, so that the Plow is turned ready for use without taking the hands from the handles. Light to draw, firm, strong, and durable. Constructed of Patent Hard Metal, which is charcoal iron, at a less price. **Illustrated Circular Free.**

**THE BELCHER & TAYLOR AG'L TOOL CO.**, Chicopee Falls, Mass.

## NOYES' HAYING TOOLS

FOR STACKING OUT IN FIELDS OR MOWING AWAY IN BARRIS.

Save labor and money. Are simple, durable, and cost but little.

No trouble in getting over high beams, or to the end of deep bays.

Hundreds are in use.

Anti-Friction Hay Carrier. Grapple Fork. Wood Pulleys, Floor Hooks, etc. Send for circular and designs for tracking barns to **U. S. WIND ENGINE & PUMP CO.**, Batavia, Kane Co., Illinois.

## THE Minnesota Chief.

## The Best Thresher on Wheels.

It is not a Vibrator, neither is it an Apron Machine. It is wonderfully simple in its arrangement. It is admirably perfect in its threshing and separating qualities. It saves all the grain, and cleans it ready for market. It runs easily, is constructed durably, is finished beautifully, is the most economical, least expensive, and altogether the most satisfactory machine in the market.

It will handle wet grain as well as dry. In threshing Flax and Timothy it has no equal, threshing and cleaning both as well, and nearly as rapidly as Wheat, and requires no change except the sieves. It has more square feet of separating and cleaning surface than any other machine made, and cannot be overloaded. It is both over and under blast at the same time.

Our Clover Hauling attachment is a new and very desirable feature. It does the business more rapidly and better than an exclusively Hauling Machine.

Separators of the various sizes fitted for steam or horse-power, as desired.

An improved Pitt's power, an improved Woodbury power, and the Edward equalizing power, all mounted on four wheels, are manufactured by us, and are not surpassed by any in the market.

We are also prepared to furnish first class Portable Engines with our Separators.

For price list and circulars, address the manufacturers, **SEYMOUR, SAEIN & CO.**, Stillwater, Minn.

## NEW MUSIC BOOKS.

**COMMON PRAISE HYMNAL.** (30 cents, flexible covers), by J. H. WATERBURY, is a wonderfully good, compact and cheap collection of 150 standard hymn tunes, 170 standard hymns, and numerous chants. Examine for Sunday School or Congregation.

**NEW FLOWER QUEEN.** (75 cts.) by G. F. ROOT. Just revised and improved by the author, and is a fine cantata for May and Flower Time.

**EMERSON'S ANTHEM BOOK.** (\$1.25.) by L. O. EMERSON. A very superior Anthem Book.

**WHITE ROBES.** (30 cts.) Best Sunday-school Song Book.

**ROBINSONADE.** (50 cts.) Good music, a poem to recite, tableaux, and amusing action, founded upon the adventures of "Poor Robinson Crusoe." By A. DARR.

**Temperance Jewels.** (35 cts.) Best Temperance Book.

**FIELD OF HONOR, or Pre aux Clercs.** (\$2.00) by HEROLD. A famous opera. Just published.

**THE SORCERER.** (\$1.00.) SULLIVAN'S Best Opera.

Any book mailed for retail price.

**OLIVER DITSON & CO., Boston.**

**C. H. Ditson & Co., J. E. Ditson & Co.,**  
843 B'dway, New York. 1228 Chestnut St., Philadel.

## ZIMMERMAN

**FRUIT AND VEGETABLE  
DRYER & BAKE OVEN**

Over 11,000 in use.

**The BEST in the Market.**  
Made entirely of Galvanized Iron

**AGENTS WANTED.**

Send for Circular Address

**ZIMMERMAN FRUIT DRYER CO.,**  
Cincinnati, Ohio.

## EVAPORATING FRUIT.

**SENT FREE** Treatise on improved methods. Tables, yields, prices, profits, and general statistics.  
**AMOS STOFFER, Chambersburg, Pa.**

**A Valuable Patent Under Date of Jan. 20, 1889.**  
**BOWLUS'S PATENT**

**Ornamental Brass Spring Trace Fastener.**

Can be attached to any Buggy or Spring Wagon, old or new, in three minutes. Saves time and trouble. Try them and be convinced. Will send to any address, post-paid, one (1) pair on receipt of \$1.20, or 10 pair \$1.10 each. Agents wanted. Address M. M. BOWLUS, Bowlusville, Clark Co., O.

## Scribner's Lumber & Log-Book.

**OVER HALF A MILLION SOLD.** Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and plank, by Doyle's Rule, cubical contents of square and round timber, stave and heading bolt tables, wages, rent, board, capacity of cisterns, cord-wood tables, interest, etc. Standard Book throughout United States and Canada.

Ask your bookseller for it, or one sent by me for 35 cents, post-paid.

**G. W. FISHER,**  
**P. O. Box 238, Rochester, N. Y.**

## Wonder-Box

Contains 12 shts. Letter Paper, 12 Envelopes, and over 500 articles—Games, Transfers, Embossed Pictures, Mottos, Comic Cards, Dolls' Heads, Soldiers, &c., all in a box, 42 cts.; by mail, 53 cts. Catalogue and Picture Card free. **J. JAY GOULD, Boston, Mass.**

**NEW FLORAL AUTOGRAPH ALBUM.**—Illustrated with Birds, Scrolls, Ferns, Flowers, etc. (48 Pages). Covers and edges elegantly Gilded; also 47 select quotations, all for 15c.; including Outfit 75 styles Photograph and Visiting Cards, 25c., post-paid (stamps taken). Agents wanted. **G. W. BOGEMSDEN, West Haven, Conn.**

**AGENTS WANTED EVERYWHERE** to sell the best Family Knitting Machine ever invented. Will knit a pair of stockings, with HEEL and TOE complete, in 20 minutes. It will also knit a great variety of fancy work for which there is always a ready market. Send for circular and terms to THE TWOMBLY KNITTING MACHINE CO. 409 Washington St., Boston, Mass.

electricity, locomotives, birds, horses, etc., etc. Population, size, and religions of the world, etc. This remarkable book sent, post-paid, for 42 Cents. Two for 75 cts. Agents wanted. Price per dozen or hundred given on application. Address **PATTEN & WADE, Publishers, 47 Barclay Street, New York.**

## World's ONLY Manufacturer of WHEEL CHAIRS

Exclusively.—ALL Styles and Sizes for  
**Invalids and Cripples**

Self-propulsion by use of hands only, in street or house. Comfort, durability, and ease of movement unequalled. Patented and Maker of the "Rolling Chairs" pushed about at the Centennial. For Illustrated Catalogue send stamp and mention *American Agriculturist*.  
**HERBERT S. SMITH, 32 Platt St., New York.**

## AGENTS WANTED to Sell the NEW BOOK, FARMING FOR PROFIT

**TELLS HOW TO**  
Cultivate all the Farm Crops in the Best Manner; Breed, Feed and Care for Stock; Grow Fruit; Manage Farm Business; Make Happy Homes, and  
**How to Make Money on the Farm.**  
Every Farmer should have a copy. 860 Pages. 140 Illustrations. Send for circulars to  
**J. C. McCurdy & Co., Philadelphia, Pa.**

## WORLD FAMOUS WOMEN

Types of Female Heroism, Beauty, and Influence, from the Earliest Ages to the Present Time. Magnificently Embellished with Full-page Steel plate Engravings. General and Canvassing AGENTS WANTED.  
Paying Employment for Young Men, Ladies, Teachers and others in every county. \$50 to \$75 per month. Send for circular and terms.  
**P. W. ZIEGLER & CO., Philadelphia, Pa., St. Louis, Mo., Cincinnati, O., or Chicago, Ill.**

## New Cook Book

**PLAIN and FANCY COOKING.** A book of 120 pages and over 400 carefully tried receipts by a practical housekeeper. It teaches how to prepare nice dishes at a moderate cost, and contains all that any housekeeper can desire. Also contains a carefully-prepared chapter on Cooking for Invalids. Price, postpaid, only 25 cents. Agents wanted. Price per dozen or hundred given on application. Address  
**J. L. PATTEN & CO., 7 Barclay St., New York.**

**64 PAGE AUTOGRAPH ALBUM.** Illustrated with 32 PEN SCROLLS, BIRDS, MOTTOES, FERNS, new Japanese Designs (JAPANESE COVER) & 100 Album Quotations, ALL FOR 1-0c. Stamps taken. **J. F. INGALLS, Lynn, Mass.**

**Elegant Photograph Visiting Cards,** becoming very popular and are really nice. Send your picture (photograph preferred) and we'll send you, post paid, 1000 beautiful glossy cards, with name and photograph thereon, for only 50c. (currency or stamps). Send good picture to copy from, and we guarantee satisfaction. Agents wanted, outfit 15c. Address  
**NATIONAL PHOTO CARD CO.,**  
West Haven, Conn.

**20 GOLD and SILVER CHROMO CARDS, WITH** name, 10c., post-paid.  
**GEO. I. REED & CO., Nassau, N. Y.**

**20 NEW GOLD and SILVER CHROMOS 10 CTS.** with name. Silver or gold taken.  
**J. B. HUSTED, Nassau, N. Y.**

**52 Gold, Crystal, Lace, Perfumed, and Chromo Cards** name in Gold and Jet.  
**CLINTON BROS., Clintonville, Ct.**

**50 Elegant Cards. New Chromo, Shells, Gilt-Edge,** etc., with name, 10 cents.  
**G. A. SPRING, East Wallingford, Ct.**

**50 CHROMO, SNOWFLAKE, AND LACE CARDS,** with name, 10c. 40 all chromos, 10c.  
**STAR PRINTING CO., Northford, Ct.**

**EMPLOYMENT—LOCAL or Traveling** State which preferred. Also SALARY per month. All EXPENSES advanced. WAGES promptly paid. **SLOAN & Co. 306 George St. Cincinnati, O.**

**FRIENDS! If you are in any way interested in  
BEES OR HONEY,**

We will with pleasure send you a sample copy of our **MONTHLY GLEANINGS IN BEE CULTURE**, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Artificial Comb, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. Nothing Patented. Simply send your address on a postal card, written plainly, to  
**A. J. ROOT, Medina, Ohio.**

**THE CLOVER-LEAF,** a 4-page, 24-column farmer's paper, containing valuable information on the culture and harvesting of clover for seed. Sent free to every farmer sending us his name.  
**BIRDSELL & CO., South Bend, Ind.**  
Say you saw this in the *American Agriculturist*.

**The Best ILLUSTRATED DICTIONARY** ever made for the price. 706 pages. 30,000 words, accurately pronounced and clearly defined. Hand-somely bound in cloth, with gold embossed title and ornamentation. It has, in addition, an alphabetical list of foreign words and phrases, also of American geographical names, with their derivation and signification. Popular names of American states and cities. Abbreviations in general use. Words used in the metric system. Divisions of the Aryan languages. Languages and alphabets of the world. Distances traveled in a second by sound, light, and various facts in regard to man, to women, to light, to the ocean, etc., etc. Population, size, and religions of the world, etc. This remarkable book sent, post-paid, for 42 Cents. Two for 75 cts. Agents wanted. Price per dozen or hundred given on application. Address **PATTEN & WADE, Publishers, 47 Barclay Street, New York.**

containing a great variety of items, including many good hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 179.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "*American Agriculturist*," containing articles referred to in the "*Basket*" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the *American Agriculturist* are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist* (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Is Corn the Cause of Contracted Hoof?**—"B. J. G.," Nashua, Iowa. Corn is a highly carbonaceous food, and as this kind of food is used chiefly for maintaining the animal heat, too much of it is apt to cause disturbance of the system. The result of overfeeding with corn, is to make an animal feverish, and the feet of a horse are tender spots, on account of the sensitiveness of the laminae. This is perceived in the easy foundering of a horse, by overfeeding. A result of fever in the feet, is contracted hoof; so that corn may be the cause of contracted hoof. To feed some bran will avoid this.

**Coal Oil Barrels.**—"W. W. H.," Blair Co., Pa., wishes to so cleanse barrels which have had coal oil (kerosene) in them that they may be used for vinegar, cider, etc. He has tried burning them out, but without success. If a thorough burning will not make them fit for use, we doubt if anything else will. If any reader can help our friend, let us hear from him.

**Sheep Disease in England.**—The cable brings an account from the U. S. Consul at Gloucester, Eng., of a serious outbreak of a disease among sheep, in several localities. In this instance, it is "Rot," or "Sheep Rot," and quite distinct from Foot Rot. The Rot is due to "Flukes," which are leech-shaped worms, often found in the gall-bladder, or ducts and liver of sheep. Small numbers of these may be present without manifest injury to the sheep, but when they occur in large numbers, the whole system of the animal is so disorganized, that the term "Rot," best expresses its condition. It is caused by poor food, low damp pastures, and water from ponds and pools. When it occurs, its course is rapid, and no treatment will save the animal. Prevention is possible, by avoiding the causes. One part of the life of the Fluke is passed within the bodies of fresh water snails, etc., and from these it in time reaches the interior of the sheep; for this reason it is important to supply sheep with well-

water, or other water free from these animals. Sheep in which the attack does not amount to Rot, have been cured by a mixture consisting largely of Salt and Spirits of Turpentine. Indeed, the free use of Salt is regarded as an important preventive. We learn from a correspondent in Oregon, that Rot has within a short time made its appearance in some localities in that State.

**Bronzed Oranges.**—The fruit in the Orange groves of both Florida and Louisiana has of late years been much discolored. The rind becomes, either in part or completely, colored a dark brown. The cause of this discoloration has not thus far been ascertained, a careful examination by those expert with the microscope having failed to detect anything like fungus, the cause of so many fruit troubles. It does not appear to prevent the fruit from coming to maturity, or to in the least affect its quality. We recently saw some boxes unloading, on which was marked in conspicuous letters, "Genuine Florida Bronzed Oranges," with the grower's name, etc. This is shrewdly making "a virtue of necessity," and it may be that those whose groves are now free from the defect will be looking for a method by which their oranges can be "bronzed," and thus increase in value.

**The Cost of Tillage.**—Other things being equal, that land which is tilled with the least expense, is the best land. It is not the size of the crop that determines the profit in farming, but the excess of the income over the outgo. If it costs more to keep a corn field perfectly clear from weeds than the value of the increase of the crop caused by that culture amounts to, then, so far as the corn crop is concerned, such excess of corn is a loss. But the influence of the care bestowed on one crop upon those that follow it, must not be overlooked. It may be the best system that grows a certain crop at a loss in order to raise succeeding ones at a profit. The value, and, therefore, the cost, of tillage, in a well established system, depends very largely on the time and place that is done.

**Snakes Swallowing their Young.**—While it is a well established fact that most snakes do swallow their young, it has been doubted that this was done by venomous snakes. We recently gave an account, showing that Rattle Snakes have this peculiarity, and now comes Mr. C. C. Lohingler, of Alleghany Co., Pa., with a case, or rather cases, in point, which must add the Copperhead to the list of swallows of their young. Mr. L.'s account is given with great precision and circumstance of time, place, and persons, but as we have no reason to doubt his statements, we need give only the results. On Aug. 26th last, on going home from the station he came across a boy of 14, who had just killed four large Copperheads, which he had found together at the foot of a stone wall. Noticing that two of the snakes were much puffed out, he opened the largest with his penknife, and found its belly full of young Copperheads; this led to the opening of all four, and every one had young Copperheads, and he took out in all 34 young snakes from four old ones, but did not think at the time to note the number from each. The young snakes were from  $\frac{3}{4}$  to 6 inches long, and all showing more or less life. This testimony added to that given last month would seem to be sufficient to settle the question that venomous snakes, like others, do swallow their young.

**Teeth as an Index of Age.**—"B. A. B.," Cervo-Gordo Co., Ia. The teeth are an indication of the age of animals to a certain extent. They are not exact to a month, or even six months. Animals differ in precocity, and some have their teeth earlier than others. In a heifer, the second permanent incisor appears at 28 to 32 months, the fifth molar appears near the end of the second year, in the back part of each jaw; in the course of the third year, the second permanent molar appears. The third permanent incisor comes after 3 years, but it may not come until near the end of the 4th year. A chart of the teeth may be had at this office, (price \$1, post paid), by which their manner of growth can be understood.

**Sheep Keeping in Kansas.**—"F. M. M.," Girard Co., Ky. Sheep can be kept easily in Western Kansas. About Dodge City is a suitable locality, as it is not thickly settled. For a flock of 1,000, a capital of at least \$3,000 will be required. The sheep can be purchased at Denver, Colorado, and driven slowly across the country to Kansas. One man can care for 2,000 sheep.

**A Wisconsin Farm Going to Louisiana.**—A Grant Co., Wis., farmer writes that he does not like to see hundreds of acres of the very best land, all the manner and sometimes the crops too, washed into the Mississippi and carried down to New Orleans, probably to help form the Deltas. This is a question in agricultural engineering, and the remedy can only be suggested by an inspection of the locality. The situation of the land may be such that it could be thrown into terraces by the plow, and thus prevent washing. Our correspondent does not state whether the land is the river "hot-

tom" and the loss arises from overflow, when diking would be the remedy, or is steep river banks and the washing is from heavy rains. It may be the best use of such land to put it into grass, and thus hold the land.

**Sulphur Fumes for Ants.**—"E. M. S.," writes from Perth Amboy, N. J., that when he lived in Texas, parties went about with apparatus for destroying ants. It consisted of an arrangement for forcing the fumes of burning sulphur into the nests, and was found very effective, though the price charged by the operators was regarded as extravagant. A similar method has been found useful in California, for the destruction of ground squirrels. Those who have failed with all other methods for ridding their grounds of ants, may act upon this hint. An ordinary hellows could be rigged up to answer.

**Out of His Name.**—It is very annoying when every pains has been taken, to find, when it is too late, that an advertisement which one man has paid for, is accredited to some other man. Mr. G. H. Rathbun tried recently to tell people that he sold Plymouth Rocks and other fowls at Hartford Conn., but when the advertisement was published, it was made to appear, that it was one J. H.—another Rathbun altogether. G. H. Rathbun is the man who has the famous chickens.

**A Feed Rack.**—A reader sends sketches of a cheap feed rack and says: "I use 2 by 4-inch scantling, seven feet long for the posts, of which there are three pairs in a 16 foot rack. They should be bolted together at the top; and it is better to bolt the scantling on too." A 2 by 4 scantling is put on each side above the bottom board, shown in an end view of the rack in figure 1. The posts should project a few inches below the bottom board. The arrangement and position of these posts, makes it impossible for stock to get their feet into or upset the rack. It can be used for a part of a fence, around stacks, thou-

Fig. 1.—END VIEW.

Fig. 2.—SIDE-VIEW OF RACK.

in that case the cattle can only eat from one side, ordinarily they eat from both sides. Figure 2 shows one of the sides of the rack ready for use.

**Mucilage from Cherry Gum.**—"H. B. D.," there is a most excellent reason for your failure to make mucilage from the gum that exudes from cherry and other fruit trees—it is not soluble in water. Though fruit-tree gums, when dry, have some resemblance to the poorer kinds of Gum Arabic, they are really very unlike. Gum Arabic will completely dissolve in water, but these gums from the cherry, etc., merely swell up, but do not dissolve; no matter how much the mass is stirred and broken up, it will, after standing a while, all settle, leaving the water without any stickiness.

**Buying Seeds of Strangers.**—A correspondent in Augusta Co., Va., writes that a man passed through his and other counties "selling Swedish Clover Seed, representing it as having been introduced into Penn. in 1876, through the Shaker Seed Co." The seller has since been published in some papers as a swindler, and his seeds as those of injurious weeds. Our friend and a number of other farmers are in trouble, and fear to sow the seed lest they fill their land with vile weeds, and we are written to for information on the subject. The safety of these farmers consists in the fact that it is much easier to get seeds of useful plants than those of weeds. This chap no doubt furnished old clover seed of some sort. But why buy seeds of strangers and believe their nonsense? By consulting the catalog of any first class seed house they would have found that Swedish Clover was a regular article of their trade. Desirable novelties are not hawked about the country in this way.

**Black Leg in Calves.**—"H. T. F.," Peoria Co., Ill., writes that he has lost three sucking calves in as many weeks. "I first find them quite lame in the front shoulder, with blood gathering under the skin, which moves with the pressure of the hand. Death soon follows. Upon being skinned, the blood is black, and all next to the skin."—This trouble, called variously "Black Leg," "Black Quarter," "Bloody Murrain," (*Carbuncu-*

*lar Erysipelas*), is most frequent in young, well-fed, and rapidly growing stock. It consists of a remarkable change in the blood, with its accumulation in the shoulder, neck, breast, and near side. The disease is very rapid in its work, and a recovery from an attack is exceptional. If noticed in time, it may be prevented from taking its malignant form by changing the food to a lighter diet, and employing a purgative of 2 to 6 ounces of Epsom Salts, and a little Linseed Oil. The warm weather of early spring is the most favorable time for the development of the disease, and it should be watched for.

**Trotting Horses.**—At the close of the trotting season of 1879, there were fifty-four horses with a record of 2:30. Of these over one-half are the descendants of Rysdyk's Hambletonian. St. Julian, the fastest trotter on record,—time, 2:12½—is a combination of the trotting elements of the Hambletonian and Clay families of horses.

**English Rental Better than American Proprietary Farming.**—Here is what the owner of a farm in Wisconsin writes and we give his view of the matter. Comment is unnecessary:—"Valuable as the *American Agriculturist* is, it would be much more so, if it would leave alone comparisons between English and American farmers. The truth is this: An English Farmer on a good rented farm with any surety of holding it for any length of time, is infinitely better off than an American farmer, and is placed in a much better position to make money: that is paying a rent of \$5 to \$10 per acre annually, in England, is better than owning land in America. I know of what I speak. I have farmed in England. This is the third and last time that I have been in the United States. Probably you think me crazy—maybe I am. I am just crazy enough to go right back again and rent a farm in England. What is a rent of \$5 to \$10 or \$15 per acre in England for good land, compared to the prices they realize for products, and compared with our prices."

**An Unfruitful Vine.**—A correspondent at Dobbs' Ferry, N. Y., writes that he has an "Isabella" vine 8 or 10 years old that blooms abundantly every year, but bears no fruit. He has tried severe pruning, no pruning, and enriching the soil, but all to no purpose, while other vines of the same variety near by have an abundance of fruit. Our friend does not wish to destroy the vine, as it affords shade where it is needed, and asks: "What is the trouble with the vine?"—We think he has answered the question very completely: It does not bear. The vine may be a chance seedling, and it is a very common thing for seedling grape-vines to bear only staminate or sterile flowers. Or it may be a sport; it sometimes happens that one branch of a vine will bear different leaves, or larger or differently shaped or colored fruit from the rest of the vine. In this case a cane may have sported in the direction of producing only staminate or male flowers, and that cane was used in propagating. We should set a new vine or vines, to take the place of this; as the new vines get large enough to produce shade, cut away a part of the old one; in two or three years it can be replaced by other vines, and no perceptible amount of shade be lost, while fruit will be gained.

**Corn Cobs.**—During the past six months corn cobs and the meal from them have attracted considerable attention. Not many years ago they were thought worthless as an article of food, and are now generally thrown away. Of late a number of analyses of corn cobs have been made, all of which are much in their favor. Prof. Stockhardt, of Germany, rates the nutritious value of cob meal as high as that of fresh potatoes, and says that it is more digestible than straw. The next question, and the one which as yet does not seem to be answered, is: What is the influence of this meal upon the animal? Does it clog the panicle as claimed by some? The chemistry of cob meal is one thing and the practical feeding value of it, is another; will they both agree in its being an important addition to the list of our feeding stuffs? Any analysis may show a nutritive value that the animal's stomach fails to discover. The value to the farmer of cobs, as a feeding stuff, can only be ascertained by accurate experiments in feeding. If any such have been made they should be made public.

**Our Field Experiments.**—Prof. Atwater writes "In the descriptive pamphlet prepared to go with the Experimental Fertilizers offered by the *American Agriculturist*, I have taken pains to explain about the experiments, and how to make and interpret them. I shall be happy to receive questions and suggestions, and will reply as promptly and fully as my time will allow." Address communications to Prof. W. O. Atwater, Middletown, Ct.—[Eds.]

**Toads Eating Bees.**—A French observer, M. Brunet, has seen a single toad in his garden catch, and devour, twelve honey bees in rapid succession. Upon moving the toad to some distance from the hive, it returned to its attacks upon the "hot-footed" insects.

## Catalogues Received.

## SEEDSMEN.

WM. H. CARSON, 125 Chambers Street, New York. Through some oversight this was not acknowledged at the time it was received, though it came among the earliest. It is not too late to say that it is one of the very neatest and fullest, while in the way of novelties it is in the foremost rank.

FRANK FORD, Ravenna, Ohio. Seed Potato list and Alpha Tomato.

AARON LOW, Essex, Mass. A full and illustrated list, with Low's Hybrid Squash and other specialties.

T. J. SIMONSON, 63 Barclay Street. An abridged list of Seeds and Plants.

ROBERT VIETCH & SONS, New Haven, Conn. A full Seed catalogue, to which a large Plant list is appended.

## NURSERYMEN.

BAIRD & TUTTLE, Bloomington, Ill. This is the Nursery established by F. K. Phenix, and appears to be as full as formerly.

R. J. BLACK, Bremen, Ohio. Besides the well known varieties, a remarkable list of New and Rare Apples, Dye-house Cherry, etc.

GEO. W. CAMPBELL, Delaware, Ohio. Grape Vines, including novelties, other Fruits and Flowers.

R. DOUGLAS & SONS, Waukegan, Ill. A special list of very fine Evergreen Seedlings.

ELLWANGER & BARRY, Rochester, N. Y. Descriptive catalogue of Ornamental Trees, Shrubs, etc., as full and as wonderful in its way as the Fruit list noted last month.

G. H. & J. H. HALE, South Glastonbury, Conn. Small Fruits, Champion Quince, etc.

FARLEY & ANDERSON, Union Springs, N. Y. Fruit and Ornamental Stock. The Duchess Grape a specialty.

A. HANCE & SON, Red Bank, N. J. A full stock in every department, and several specialties.

GEO. S. JOSSELYN, Fredonia, N. Y. Grape Vines and Small Fruits.

JACOB W. MANNING, Reading, Mass. General stock, Evergreens a specialty. Various novelties.

THOMAS MEEHAN, Germantown, Pa. A wonderfully full collection, with many rarities.

E. MOODY & SONS, Lockport, N. Y. Wholesale lists at very low rates.

WILLIAM PARRY, Cinnaminson, N. J. Small Fruits, with several new varieties of Fruit and Ornamental Trees.

J. A. VAUGHN & CO., Carver, Mass. General collection of Fruit and Ornamental Trees.

G. ZIMMERMAN & SON, Buffalo, N. Y. An illustrated catalogue of Fruit and Ornamental stock.

## FLORISTS.

N. ADMIRAL, Danville, Ill. Greenhouse and Bedding Plants in great variety.

BAIRD & TUTTLE, Bloomington, Ill. A large and full illustrated Plant catalogue.

G. R. CLARK, Scranton, Pa. Besides Greenhouse Plants makes a specialty of Vegetable Plants.

EDWARD GILLET, Southwick, Mass. Native Perennial Plants, Shrubs, Ferns, etc.

HOOPES BRO. & THOMAS, Westchester, Pa. Although the Greenhouse business is secondary to that of the Nursery, the list is as large as if this were the sole business.

HOVEY & CO., 16 South Market Street, Boston, Mass. Very full, and includes the wonderful new Camellias.

DAVID LITTLE & CO., Plattsburgh, N. Y. A large stock, including novelties.

TYRA MONTGOMERY, Mattoon, Ill. General Greenhouse and special Geranium catalogues.

JOHN SAUL, Washington, D. C. A catalogue of over 120 pages, with the usual share of Rare and New Plants, besides a splendid Rose list.

GEORGE SUCH, South Amboy, N. J. Spring catalogue of Bedding Plants, Gladioli, etc., as neat in appearance and as rich in contents as its predecessors.

W. B. WOODRUFF, Westfield, N. J., adds to Bedding Plants, Cabbage, Tomato, and others, thus bleuding the useful with the sweet.

## FOREIGN CATALOGUES.

STEELE BROS. & CO., Toronto, Canada. A very full illustrated "Seed Annual."

D. LUCCHETTI & CO., Milan, Italy. Field and Garden Seeds, and Seeds of American Grapes.

## FERTILIZERS.

H. J. BAKER & BRO., 215 Pearl Street, N. Y. Forester's Complete Manures.

MATFIELD FERTILIZER CO., 13 Doane Street, Boston, Mass. A treatise on the Matfield Fertilizers, and directions for use.

MICHIGAN SALT ASS'N, Saginaw, Mich. A Treatise on "Salt as a Fertilizer."

## LIVE STOCK, POULTRY, ETC.

ARMSTRONG & BOGMAN, Providence, R. I. Pea Comb American Sebrights.

SAM'L CUSHMAN, Pantucket, R. I. White Leghorns.

W. E. FIELD, Richland, N. Y. Poultry, Tront, and Bees.

GEO. S. JOSSELYN, Fredonia, N. Y. Fowls, Ducks, and Geese.

F. B. REDFIELD, Batavia, N. Y. Polled Angus and Short Horn Cattle, and Trotting Horses.

W. L. MALLOW, New Holland, Ohio. Ayrshire Cattle, Berkshire Pigs, Cotswold Sheep and Poultry.

L. C. ROOT & BRO., Mohawk, N. Y. Italian Bees, and all appliances used in Bee-keeping.

## MACHINERY AND MISCELLANEOUS.

AMERICAN STEAM APPLIANCE CO., 12 and 15 Park Row, N. Y. Feed Governors, Water Indicators, etc.

BLTYMER MANUFACTURING CO., Cincinnati, Ohio. This, the oldest establishment engaged in making Sorghum and Sugar machinery, is ready to meet the renewed activity in Sorghum culture.

BOOMER & BOSCHERT, Syracuse, N. Y. Full descriptions and illustrations of their remarkable Cider and Wine Presses.

H. B. GRIPPING, 70 Cortlandt Street, N. Y. Farm Implements, Fertilizers, Chemicals, etc.

ALLEN GOVERNOR CO., Boston, Mass. Governors for Steam Engines.

A. & F. BROWN, 57, 59, and 61 Lewis Street, N. Y. Hangers, Pulleys, and other machinery.

EUREKA MOWER CO., Towanda, Pa. Mowing machines.

JAS. W. QUEEN & CO., 924 Chestnut St., Philadelphia, Pa. Microscopes, Telescopes, etc.

GEO. W. TAFT, Abington, Conn. Benefactor Road Scraper.

WM. SELLERS & CO., 79 Liberty Street, N. Y. Shafts, Hangers, Pulleys, and other machinery.

WILLSON & SONS, Columbus, Ohio. Cast-Steel, Spiral Spring Whiffle Trees.

WORTHINGTON & COOLEY, Jackson, Mich., make Garden and Farming Tools, and issue a beautiful catalogue.

## ADVERTISEMENTS.

University of the State of New York.

**American Veterinary College.**

141 West 54th St. NEW YORK CITY.

The regular course of lectures commences in October, each year. Circular and information can be had on application to

A. LAUTARD, M.D.V.S.,

Dean of the Faculty.

**Only \$98.00**  
with **STOOL** and  
Instruction Book.

## Beatty's Offer for Thirty Days.

This Beautiful Piano Upright Cabinet or Parlor Organ. (like ent) New Style A, or No. 2400. Dimensions—Height 54 inches, Depth 24 inches, Length 52 inches. **Three (3) sets of Golden Tongue Reeds, Thirteen (13) stops.** (1) Violin, (2) Echo, (3) Viola, (4) Diapason, (5) Melodia Forte, (6) VOX CELESTE, (7) GRAND ORGAN, (8) Celestina, (9) Flute Forte, (10) Melodia, (11) Flute, (12) Dulcet, (13) VOX HUMANA or TREMULO. **Five Octaves. Upright Bellows,** with immense power. **Lead Stands** at each end. **Beatty's Improved Knee Swell** and **Beatty's New Excelsior Grand Organ Knee Swell.** Magnificent highly finished Black Walnut Case and Elegant French Veneered Panels latest design extension top with beautiful music receptacle. All late improvements. Weight when boxed about \$35 lbs. This Organ contains **Beatty's New Vox Celeste Stop**, which is by far the sweetest and most perfect that has ever been attained. Charming is the universal exclamation of critics and lovers of sweet music who have heard this combination. The sudden burst of harmony thrown out by the Beatty Grand Organ Excelsior Knee Swell, from the scale being performed by a professional, is inimitable; all things considered, this instrument is the finest Cabinet Organ in America. I challenge its equal. Beware of imitation. Buy only the genuine Beatty.

Regular Retail Price asked for such an instrument by the Monopolists' Agents, about \$375.00.

I will sell this Beautiful Organ during the next 30 days in order to have it introduced, with a **PLAIN \$3 ADJUSTABLE STOOL**, and **Instruction Book** thrown in, (which will be shipped with the instrument) for **ONLY \$98.00!**

Can be shipped on an Hour's Notice. Please send your order by letter or telegraph. No money required until you are entirely satisfied. Pay for the instrument only after you have fully tested it at your own home. If it is not as represented, return it at my expense, I paying freight both ways. This certainly is a fair offer. Remember that this offer is not good after the 30 days are up, and that I positively will not deviate from this price.

## FULLY WARRANTED FOR SIX YEARS!

I want this instrument more generally introduced, hence this unparalleled offer. It is about the actual cost of manufacturing. **ORDER AT ONCE**, as every Organ when introduced in a new locality sells others. My instruments are first-class and just as represented. **It is a Standing Advertisement.** Hence I can give you a splendid bargain, by selling you one first one at about cost. You will do well to accept this offer. At this writing our order No. stands **72,819**, (Seventy-two thousand, eight hundred and nineteen) of **Beatty's Celebrated Pianos and Organs** in actual use throughout the civilized world, and I challenge any one to show one that does not give perfect satisfaction. Sales now very large, constantly increasing at a rapid rate. **The most successful house in America.** More unsolicited testimonials than any manufacturer. Send for list of names of persons who are using my instruments everywhere, some may be in your neighborhood, whom you may know. I have extended my sales now over the entire world. **The Sun shines nowhere but it lights my instruments.** Since my return from an extended tour through the Continent of Europe, I am more determined than ever that no city, town or village throughout the entire civilized world shall be unrepresented by my celebrated instruments. Beware of imitations! My great success has brought into existence hundreds of irresponsible imitations. Beware! Buy the best but avoid the monopolists and irresponsible houses. **This is the only Establishment in the world that uses the Celebrated Golden Tongue Reeds!** The greatest invention of the 19th century. Having been **Elected Mayor** of my city by an overwhelming majority is sufficient proof of my popularity at home. **This Advertisement will appear but once**, and nothing can be saved on this instrument by correspondence. **Order now!** If you do not want one yourself, order one and make your friend a handsome present. **This is the greatest offer yet made.** Illustrated newspaper with much information about cost of Pianos and Organs, sent free. **Show this splendid Offer to your Neighbors.**

ADDRESS ALL ORDERS TO **DANIEL F. BEATTY, Washington, New Jersey.**

None is the time to order, labor and material are advancing. **NEW PIANOS, WITH STOOL, COVER AND BOOK FROM \$210 to \$1,600.**

**BEATTY.**

## READ WHAT IS SAID OF BEATTY'S ORGANS.

J. L. Everett, Esq., Cashier National Broadway Bank, New York City, writes: "Organ received. As I am fully satisfied with the instrument, I remit without further delay. I have not thought it necessary to call in experts to test it. All my family are delighted with it." Send for our list of testimonials from persons from all parts of the world who are using Beatty's Celebrated Pianos and Organs.

**NOW IS THE TIME TO ORDER.** Labor and material are advancing. Prices for Musical Instruments can never be lower. ADDRESS ALL ORDERS TO

**DANIEL F. BEATTY, Washington, New Jersey.**

# \$1000. REWARD

For any Washing Machine that will Wash Cleaner, Quicker, with Less Labor and Wear and Tear of Clothes than the **ROBBINS FAMILY WASHER AND BLEACHER, PAT'D OCT. 3, '71.**

THE ORIGINAL AND ONLY PERFECT SELF-OPERATING WASHER IN THE WORLD.

No rubbing required. No more yellow clothes nor hard work on washing day. No more rubbing clothes full of holes. Seeing is believing, and if you will try it once, you will never again wash without it, nor use any other washing machine. It is THE BEST IN THE WORLD, and will wash anything from a lace curtain to a horse blanket, and can not get out of order.

Good Agents Wanted, both Male and Female, to whom Liberal Inducements are Offered. Agents can make from \$10 to \$100 per week.

## THE ART OF CLEANSING FABRICS.

is yet but imperfectly understood by thousands of good house-keepers. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash-bottles, etc., have all failed in one or more of the three essential points, namely: The saving of labor, wear and tear of clothes, or in perfectly extracting the dirt and discoloration; all of which are accomplished by the **ROBBINS FAMILY WASHER AND BLEACHER**.

## WHAT IS IT REMOVES THE DIRT?

You may ask washer-women and house-keepers, and your answer from nine out of ten will be, "Plenty of elbow-grease," or in other words, laborious rubbing upon the wash-board. And such is the case, for you first rub soap upon the cloth, and then you have to rub it in to make the dirt soluble; but does that remove it? No; to do that you must dip it in the water and rub repeatedly to force water through the fabric, again and again. That is what removes dirt after having been softened by the chemical action of the soap.

The way in which this could be most economically accomplished has been developed in the **FAMILY WASHER AND BLEACHER**, which embodies all the above points.

Mechanical devices take the entire time of a person during the whole wash, and will not remove streaks from clothes. With the Washer and Bleacher washing, baking, and housework are contemporaneous operations—the fire doing the washing and baking, while the housewife does her housework.

It is harder work to operate these mechanical devices than to use the common wash-board. They are constantly getting out of order, and wear out in a short time. They wear out clothes faster than the rubbing-board, because the friction is so much greater.

All who have tried steam wash-bottles will unite with us in saying: They do not give satisfaction.

## WE WILL EXPLAIN WHY.

As stated, *water force* is what removes dirt from the fibre of the cloth. A large body of water is required to hold in solution a comparatively small amount of dirt. Steam wash-bottles cannot accomplish the desired result. They do not contain enough water to hold the dirt in solution. While steam will not remove dirt, it is a powerful agent to assist in cleansing, because it expands the fabric, and causes the discharge of dirt and impurities from the cloth that cannot be forced out in any other way, unless by the application of heat and force of water combined.

In order to remove the dirt from *steamed* clothes, they must be washed out in water at nearly boiling heat, for if you use water at a lower temperature it causes the fabric to contract, which "sets the dirt," thus causing the clothes to turn yellow. An essential thing to be mentioned is the *rotting* of clothes by steam wash-bottles, because of the small quantity of water used.

Everybody knows that a large quantity of soap dissolved in a small body of water must necessarily form an *exceedingly strong alkali*, which, after the clothes are packed in the steam wash-bottle, is converted into steam, every moment becoming more concentrated till the clothes are removed. A few such washings and what is the result? Simply this: Your clothes fall to pieces of their own weight, and you pronounce steam wash-bottles (as they are) a failure.

THE PRINCIPLE OF THE WASHER AND BLEACHER embodies all the essential points. First, we have the desired heat which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which produces a rapid downward current of water force, through and through them, thereby removing the dirt. Third, we use a large body of water, which holds the dirt in solution. Fourth, we use but a small quantity of soap. Fifth, the washing is done by water, and *not by steam*. This process cannot injure fabrics. It cleanses thoroughly, *rinsing the clothes* being all that is required to complete the operation.

## THE CAPACITY OF THE WASHER AND BLEACHER.

There are two sizes: No. 1, the family size; No. 2, suitable for small hotels, restaurants and barber-shops, boarding-houses, etc.

The Washer is composed of metal and cannot get out of order.

The family size weighs about 5 lbs., and is only 8 inches long by 5 inches wide, and 1 1/2 inch deep.

The discharge pipe is 1 1/2 inches high over that, and is 1 1/2 inch in diameter. It throws water in a solid, unbroken stream, at the rate of 6 to 8 gallons per minute. It will work in any flat bottom boiler. It takes only 3 or 4 ounces of soap in 10 or 12 gallons of water, and will wash bed or table linen, a boiler full in 10 to 15 minutes, wearing apparel in from 10 to 30 minutes, and will remove streaks without rubbing; requires no previous preparation of the clothes, such as soaking over night. Take the clothes dry, and when the Washer gets thoroughly at work, fill the boiler as full as it will hold by gently pressing them down with a stick. Use no chemicals, only good soap and soft water. If the water is hard, it may be softened by a small piece of borax, which is harmless.

For LACE CURTAINS this Washer is invaluable. It cleanses them as no other process can, and without the slightest danger of injury.

No. 2, or small hotel size, is 8 1/2 in. long, 7 1/2 in. wide, 1 1/2 in. deep, and weighs about 8 lbs. It will work in a flat bottom boiler holding 1 to 25 gallons, and wash of average pieces from 1,500 to 2,000 per day; or it may be used in any smaller boiler that has a flat bottom large enough for it to rest upon.

For hospitals this Washer is pronounced by the medical faculty invaluable, being the most powerful disinfectant known; leaving the fabrics pure as when new. By engineers, mechanics, and scientific men generally, it is pronounced one of the most wonderful discoveries in the principle of hydraulics or water force ever brought to light. By bleachers and chemists it is said to be the most powerful method of removing dirt and vegetable matter from fabrics ever known. It is the greatest bleacher extant and for that alone is worth ten times the price.

## THE PHILOSOPHY OF THE WASHER AND BLEACHER IS THIS:

We have 5 lbs. of metal, which attains a much greater degree of heat than the water surrounding it, consequently the water *underneath* the Washer becomes hotter and more expansive than in any other part of the boiler, and is thereby thrown to the surface through the tube; thus tending to produce a vacuum under the Washer at the bottom of the boiler, into which the water is rapidly drawn.

As it passes along the channels of the Washer, the curved and contracted throats of which prevent its flowing backward, and being held in contact with the hot metal it becomes hotter and hotter, consequently more expansive and more forcible until thrown to the surface, thus producing a powerful suction beneath the clothes through which the water must pass in a rapid downward current, thereby obtaining a water force which cannot be obtained by any other method known in cleansing fabrics. Thus, we get a combination, FIRST, WE HAVE THE DESIRED HEAT. SECOND, PERFECT CHEMICAL ACTION OF THE SOAP. THIRD, FORCE OF WATER—ALL OF WHICH ARE REQUIRED TO THOROUGHLY CLEANSE AND PURIFY ANY FABRIC.

THE IMPROVED WASHER, has a perfect fitting pipe, and is a combination of metals which does not become sticky or dirty. It comes out of the boiler as bright as new.

A WORD ABOUT BLEACHING. There are few professional bleachers in the United States. The word "bleaching" implies the art of extracting vegetable or animal matter and discoloration from the various fibres which constitute all our different fabrics. This is done by a regular chemical process, consisting, first, of alkaline boilings; second, immersions in solutions of chloride of

lime; third, solutions of acids. After each process the goods receive a thorough rinsing in clear water, then last of all processes to thoroughly extract all injurious matter, comes that of *boiling in good soap and water*. This leaves the goods pure and white as snow, ready to finish for the market. Now the question arises, can those fabrics again absorb and fix all their natural discolorations? We answer no, impossible. Then why is it (asks the housewife) my clothes become yellow and discolored? There are many reasons—poor soap, hard water, careless servants, not having strength to rub out the dirt yourselves, and not being able to use water by hand *hot enough* to keep the fabric expanded to the extent which is absolutely requisite to thoroughly extract the dirt, or "bleach the clothes." Clothes should never be bleached but once, but *thoroughly washed*, and they will always be white. THE FAMILY WASHER AND BLEACHER will do it for you every time.

## THE INDUCEMENTS WE OFFER.

We want a Local Agent in every town in the United States. We know from experience that reliable, energetic men can make money selling the Washer and Bleacher in any community.

We want first-class men as GENERAL AGENTS; men capable of managing one or more counties.

To such we give a duly executed Certificate of Agency. We furnish descriptive circulars for distribution among families. Also large posters for advertising in public places. Printed directions for using are sent with each Washer.

The retail price of No. 1 WASHER, in New York, is \$5.70; No. 2 WASHER, \$5.00; No. 1, \$24.00 per dozen; No. 2, \$26.00 per dozen.

## SAMPLE, OR SINGLE WASHERS.

In States east of the Missouri and Mississippi Rivers, also in Kansas and Nebraska we will deliver at your nearest railway express office, CHARGES PREPAID, Sample No. 1 WASHER, \$3.50, Sample No. 2 WASHER, \$5.00. We will deliver, PREPAID, a No. 1 WASHER in Dakota, at Bismarck, or Yankton, for \$3.50; in Wyoming, at Cheyenne, for \$3.50; in Idaho, at Franklin City, for \$4.50; in Colorado, at Denver, or Pueblo, for \$4; in New Mexico, at Santa Fe, for \$5; in Arizona, at Prescott, for \$3.50; in Utah, at Ogden, for \$4; in Nevada, at Virginia City, for \$5; in Louisiana, at New Orleans, for \$3.50; in Arkansas, at Little Rock, for \$3.50; in Texas, at Corsicana, for \$4.50; at Texarkana, Denison, or Sherman, for \$3.50. For the Pacific coast we will deliver No. 1 at San Francisco, Sacramento, Marysville, or San Jose, for \$4. Our reason for so doing is to induce people to investigate this matter, feeling assured that a trial will secure an Agent for us.

## SPECIAL NOTICE.

As to the reliability of this Company, we refer you to the MERCANTILE NATIONAL BANK of this city, or to any Express Company in New York. Also to the Publishers of the following named well known leading journals, viz.: New York—American Agriculturist, Weekly Sun, Weekly Times, Weekly Tribune, Weekly Witness, Weekly World, Christian Advocate, Boston Youth's Companion, Chicago Inter-Ocean, Cincinnati Gazette, Toledo Blade, Springfield Farm & Fireside, all of whom have more or less frequently editorially endorsed us as well as our Washer.

In ordering, write plainly your name, post-office, county, and State. Also the name of the express office to which you wish the Washer forwarded.

CASH MUST ACCOMPANY ALL ORDERS. Remit by Post-office Order or Registered Letter, at our risk. To insure the safe delivery of all Washers ordered as above. Money may also be sent by draft on New York. Send for a sample and secure A BUSINESS THAT WILL PAY YOU WELL.

When you order or write, mention this paper. Address

**Bissell Manufacturing Co.**  
50 BARCLAY STREET, NEW YORK.

## W. S. BLUNT'S Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE "MEDAL OF SUPERIORITY," The highest award of the American Institute for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be removed, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern **DEEP WELL non-freezing FIRE PUMP**. Also, Blunt's Sand Venturi Chamber, a complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1 1/2-inch to 4-inch suction pipe.

Send for circulars to  
**NASON MFG CO.,**  
71 Fulton and 71 Beekman St., New York.

New England Agency, **A. M. MORTON & CO.**, 25 Washington St., Boston, Mass.

## CHICAGO SCREW PULVERIZER.

**Does Pulverization pay?**

ABILENE, KANSAS, Nov. 10, 1879.  
I seeded 3,400 acres of wheat with these machines... The stand of wheat is now the best I have ever seen on now land.  
R. J. WEYMES, Trustee.

DANVILLE, ILL., Dec. 4, 1876.  
This year I harvested, on 190 acres, 6,101 bushels of wheat. In my opinion the Screw Pulverizer increased the crop one-third over what I could have got by any other method.  
D. G. MOORE.

Send for pamphlet with cuts, and over sixty letters from men who have the machine. Address,

**Chicago Scraper & Ditcher Co.,  
34 METROPOLITAN BLOCK, CHICAGO, ILL.**

## STEEL BARB FENCE,

Solves the FENCE Problem by meeting all the requisites of

**THE PERFECT FARM FENCE.**

**Every Land Owner** should not fail to examine the merits of this fence. It is cheaper than all others. Easiest handled, and in fact just what the people of the treeless States have needed for years.

**To All Inquirers.**

It is an impassable barrier, yet harmless. Prohibits trespassing. It can be put up by any one, and is compactly put up for transportation. In fact, it is the only fence dog and wolf proof.

Cheaper than Wooden Fences. Imperishable when once in place. Indestructible by the Elements. Waste no soil by SHADE. Has no Weedy Fence Borders. Shelters no Enemies of the Crops. A Protection at all seasons. It is easy of Construction. It needs no repairs. Accumulates no snow-drifts.

### A. STEEL THORN HEDGE.

Impassable Barrier. Prohibits all Trespassing. It can not be destroyed by fire, wind, or flood.

100,000 miles of Barb Fence have been erected in 1876, 1877, 1878. Agriculturists, Herdsmen, Sheep Husbandmen, Ranchmen, Vineyard Proprietors, Orchardists, Nurserymen, Railroad Companies, Road Proprietors, and all owners and occupants of soil and areas to be protected.

Manufactured by **Washburn & Moen Manufacturing Co.,  
WORCESTER, MASS., and 21 CLIFF ST., NEW YORK.**

## Powell's Iron Fence Posts

For Barb Wire, Iron, or Gas Pipe Fencing.

**Cheap, Strong, and Durable. No Digging Required.**

DIRECTIONS FOR SETTING POSTS.

First drive post with wrought iron guide in place, then drive cross-pieces through guide, which renders it more immovable than any other post, in the setting of which the ground must be displaced.

We make Line Posts, also End and Corner Posts, either painted or galvanized, and Wire Strainers of an Improved Pattern.

**ABRAM G. POWELL & CO.,  
829 Willow St., Philadelphia, Pa.**

## FRENTRESS STEEL BARBED FENCE WIRE

(Patented Dec. 14, 1875—Reissued May 22, 1877.)

**The Best and most Durable of all  
the Barbed Wires in Use.**

A sure protection, cheaper than board or rail fence, and good for a life-time. Wastes no ground. Has no weedy fence row. When the best costs no more than an inferior article, always look for the best. We claim for the Frentress a superiority over all other Wires. For Circulars and Price Lists address

**FRENTRESS BARBED WIRE FENCE CO., East Dubuque, Illinois.**

## THE LATEST IMPROVEMENT IN BARB FENCE.

The cut shows exact size of strand and distance apart of barbs. Not dangerous to horses or stock. Price the same by the pound or rod. **SAMPLES SENT FREE TO ANY ADDRESS.**  
**AMERICAN BARB FENCE CO., 60 Clark St., Chicago, Ills.**

PAT'D APRIL  
1st, 1879.

# NOVELTY INCUBATOR.

I offer this as the simplest, cheapest, most easily run, and best incubator. Daily cost of running, 3 cts. for fuel and a few minutes attention. Hatches 50 to 60 per cent almost surely. Holds 100 Eggs. Price, \$25.00.

Also NOVELTY HYDRO-MOTHER, Price \$8. A. G. ATKINS, Orange, N. J.

## THOROUGHbred AND CROSS-BREED OR GRADE JERSEY STOCK.

5 fresh cows, 4 to 8 years old, with or without calves. 5 thoroughbred Jersey Bulls, 1 to 5 years old. 5 Heifers, 8 to 11 months old. All the above are, or can be registered in the A. J. C. Club Register. 25 cross-breed heifers and cows 2 to 7 years old. These are a mixture of the two breeds, Jerseys and Ayrshires; several are now fresh, and the balance within the next two months. The best family cows ever bred, all rich milkers and butter-makers; some of them 2½ cws, beautiful in form and colors. Orders solicited for calves of either breed, deliverable when weaned and ready to ship at 2 to 3 months old. My prices range from \$45 for a high grade heifer calf, to \$400 for my best thoroughbred cow and calf. April, 1880. THOMAS FITCH, New London, Conn.

## NOW

For **SPRING and SUMMER**  
**OUT-DOOR AND IN-DOOR**

## Games and Toys.

### LAWN TENNIS.

**LAWN TENNIS** is doubtless the finest game for the family now on the market, and people who have lawns, can hardly afford to be without a set. They have never been so low in price and high in quality as this year, and even to the cheapest set, \$10, they are serviceable, lasting for years, and a game that the whole family can enter into; easily learned and affording exercise with amusement.

Write for full instructions and prices, which range from \$10, to \$60. The more expensive sets are also used for the Game of **Badminton**, which is played similarly to Tennis. The cheapest sets are of first-class make and regulation size.

Correspondence solicited.

### BAT AND TRAP.

As here represented, the articles necessary to play this game are *one bat, one ball, and the trap*. Any number of persons can engage in the game, from one to five on a side, and it can be played by ladies and gentlemen, or girls and boys. It can be played on the lawn, meadow, or any place where baseball, lawn tennis, or croquet

are played. The ground need not be smooth as for croquet. It is very fascinating, and has as much variety as any other popular game. **Rules** accompany each game, and they are easily learned.

**Price, \$2.00.**

Expressage to be paid by the Recipient.

### RABBIT TRANSIT.

This has a most lifelike movement very like that of the animal itself. It has three wheels, which prevent its being easily knocked over, and it can be used by any child old enough to walk. It is neatly gotten up, and is appropriate for an *out-door* as well as an *in-door* toy.

**Price, 50 Cents.**

Expressage to be paid by the Recipient.

Ask your nearest **Toy-Dealer** for these attractive **Toys**, or send for an **Illustrated List** of all our **Toys and Games** to  
**ORANGE JUDD COMPANY,**  
245 Broadway, New York.

ORANGE JUDD COMPANY, 245 BROADWAY, N. Y.

# AMERICAN Grape Growing AND WINE MAKING.

BY  
GEORGE HUSMANN.

PROFESSOR OF HORTICULTURE IN THE UNIVERSITY OF  
MISSOURI.

With Contributions from Well-known  
Grape Growers, giving

A WIDE RANGE OF EXPERIENCE.

ILLUSTRATED.

Professor George Husmann, the author of this volume, is the recognized authority on grape growing and wine making in the United States. His reputation has likewise extended all over Europe. When grape growing met with its disastrous collapse twelve or fifteen years ago, a few bore up under the sad reverse and labored on, hoping for better times. Of this number was Professor Husmann, who had then become prominent in the culture of the grape in that district of which Hermann, Missouri, is the center. Though obliged to give up the vineyards he had established, and to relinquish the publication of the *Grape Culturist*, a most excellent monthly journal, he still continued to prosecute his labors and investigations, which have been fitly recognized, among other ways, by his appointment as Professor of Horticulture in the Missouri State University. His first volume, published some years since, attracted wide attention. He now embodies in the present volume the results of all his labors and investigations down to the present time.

In order to adapt the work to every latitude, the author embodies the methods and opinions of eminent grape cultivators in all parts of the country. Campbell, Bateham, and Kelly (of the famous Kelly's Island), speak for Ohio. Cashin gives Maryland's experience. The author describes the noted vineyards of Crooked Lake, New York. Onderdonk speaks for the pear-line climate of Texas, and in this manner, including some of the most successful growers in California, others than the author, tell their story, each for his own locality.

The work is a complete guide for novices in the culture of the Vine, and at the same time may be regarded as a summing up of everything of importance and value bearing upon this industry. Special attention is devoted to the Phylloxera, whose destruction of the roots of vines had very much to do in bringing on the collapse referred to above, and the destruction of the vineyards of France. The experiments and discoveries of Husmann and his associates in connection with this destructive little insect, are, for the first time, presented in this volume, and will prove of incalculable benefit to the grape growing interests of this and other lands.

The book is copiously illustrated with sketches from the author, which add materially to its value.

PRICE, POST-PAID, \$1.50.

# Every

# Farmer

SHOULD READ THE FOLLOWING.

WOOSTER, OHIO, Feb. 10, 1880.

RUSSELL & CO., Massillon, Ohio.—

GENTLEMEN:—From various causes, and the bad roads, I did not use the "NEW MASSILLON" Thresher purchased from you November 24th, 1879, until to-day.

Having procured the services of Mr. Watson Langell, of Endenburg, with his engine, I started the machine this morning at my barn, one mile from Wooster. Everything went off like a top. Having threshed 40 bushels in accordance with your wishes expressed when I purchased the machine, and for my own satisfaction, as also for the satisfaction of those present, we put the machine to a thorough test, as follows: We removed the stacker and swept the barn floor, then placed the machine so that every particle of straw, chaff, and grain would remain on the floor. We then went to work. I timed the machine and handled all the wheat as it came from the thresher. We ran FIFTEEN (15) MINUTES, and threshed THIRTY-THREE (33) bushels in splendid shape. We next shook off the straw, examining it carefully for unthreshed heads; NOT A KERNEL WAS FOUND IN THE STRAW. After sweeping the floor thoroughly to get every grain, we put all the chaff and refuse through the mill, and obtained barely TWELVE ounces of wheat, careful weight. This contained every grain that fell from the thresher.

A number of threshermen, farmers, and machinists were present, also the agents of two other machines—all agreed that the test was the fairest and most satisfactory they had ever witnessed, and the "NEW MASSILLON" the only machine that would thresh with the speed shown, and not throw over grain. I am sorry some of your Company were not present.

Mr. Langell, the engineer, himself an experienced thresherman, pronounced its general behavior the best, and the power required the lightest, he ever saw in a new machine.

I have no hesitation in saying that no thresher in the world has ever equalled this record. It EQUALS JUST ONE BUSHEL WASTE IN TWENTY-SIX HUNDRED AND FORTY.

Yours truly,

[Signed]

J. H. KAUKÉ.

All those present at this test have, over their signatures, fully corroborated Mr. Kauke's statement. Mr. Kauke is so well known at home that no evidence would be better than his word. We have, in addition to this letter, an affidavit from him, taken on Feb. 14th, 1880, fully verifying the above facts. The machine used was a No. 6 "NEW MASSILLON," 30-inch cylinder, 40-inch table, and was driven by an eight-horse portable engine. It was the last one we had of our 1879 manufacture, and was out of our regular stock, and was in no point changed nor improved. It was run just as it came from the shop. We invite comparison with any test made. This machine was not represented by any party present—was tried solely to prove it.

## GRASS and GRAIN CUTTING MACHINES.

AWARDED THE CROWN OF HONORS  
IN THE FACTORY AND IN THE FIELD, BY  
EXPERT MECHANICS AND PRACTICAL FARMERS.

For Lightness of Draft. For Excellence of Construction.  
For Superiority of Execution. For Simplicity and Durability.

AND FOR

New and Valuable Features never before Combined in Harvesting Machinery.

### THE NEW CHAMPION MOWER.

The new mechanical device for giving to the knife bar a rapid reciprocating motion, is one of the wonders of modern mechanism, and after years of the severest trial has proved its superiority. It runs without noise, and with extraordinary smoothness and regularity. The entire power exerted by the horses is applied directly to actuating the knife; hence, while it is the lightest draft, it is the strongest cutting machine in use, as has been repeatedly proven in the mowing of swamp lands, which had never before been mowed, because no other machine could be found that would do it. The Cutter

Bar may be raised bodily to a height of twelve inches horizontally, or be thrown up at any angle, or to a vertical position, all without throwing the machine out of gear, or stopping the team. The bar may also be folded and secured for leaving the field without the necessity of the driver leaving his seat. The perfect control which the driver has over the bar adapts the machine for use in the worst kind of mowing, readily clearing trees, stone heaps, or other obstructions.

### THE CHAMPION SINGLE REAPER.

This Harvester is expressly designed to meet the wants of farmers who cut an unusually large amount of grain. The advantages of this machine are the width of cut and lightness of draft, two very essential features in a Reaping machine. From twelve to twenty acres of grain can be cut down in a day. The difficulty heretofore with all Single Reapers was the very heavy side draft and heavy weight, incident to one wheel harvesters. These two faults have been completely eradicated in the Champion Single Reaper, and we are prepared to furnish the farmer with a Reaping Machine that will cut a swath of six feet without side draft, while the machine itself will not exceed in weight the smallest pattern of the ordinary combined machines, cutting an average swath of four feet. It is estimated by the most competent Judges that over one-half of the Hay and Grain Crop in the United States is harvested with

### CHAMPION MOWERS AND REAPERS.

REMEMBER, under no circumstances should you buy a Mower or Reaper, until you have seen THE CHAMPION. When ever you hear of one of these machines in your vicinity, do not fail to examine it thoroughly.

VOLUME XXXIX.—No. 6.

NEW YORK, JUNE, 1880.

NEW SERIES—No. 401.

THE YOUNG STALLION CLAY HAMBLETONIAN.—DRAWN BY EDWIN FORBES.—Engraved for the American Agriculturist.

The American trotting horse has been produced from a variety of elements that have been blended to secure a high development of what has been termed the "trotting instinct." The most celebrated sires to which the established trotting families trace their origin were, with few exceptions, thorough-bred, or with a large preponderance of thorough-bred blood. With the inherited nervous force of these sires was combined an aptitude for trotting action, that has been intensified by systematic training and selection during the past half century with the most satisfactory results. The first trotting match in America was made in 1818, for a stake of \$1,000 against time. It was won by "Boston Blue" in the then unprecedented time of three minutes. Now, the trotters having a technical record of 2.30 and less are numbered by hundreds, while "St. Julien" has made his mile in 2.12½. Breeders of trotters, although favoring certain strains of blood, have considered the performance of the animal as the test of excellence, and as the best performers

have descended from a few favored sires, the blood of these has been mingled to a greater or less extent in many of the celebrities of the day.

In the stallion "Clay Hambletonian," the property of Ira S. Gardner, Johnsons, Orange Co., N. Y., whose portrait is given above, the blood of two prominent families is represented—the Hambletonians and Clays. His sire, "Mapes' Hambletonian," was by "Rysdyk's Hambletonian," the celebrated progenitor of the Hambletonian family, that deservedly stands first in popular favor. His dam, the fast trotting mare, "Nettie Clay," is a daughter of "Sayer's Harry Clay," and her dam traces a lineage through "Highlander" and "Duroc," to imported "Diomed." "Sayer's Harry Clay" was by "Neaves' Clay," he by "Cassius M. Clay," and he by "Henry Clay," who was descended from "Young Bashaw." The dam of "Sayer's Henry Clay" was by "Bellfounder," the noted Norfolk trotter imported in 1822. Until within a few years the Clay family has not been appreciated by breed-

ers of trotters, but the great success of Hambletonian sires with the daughters of "Sayer's Harry Clay," has shown the value of this strain of blood. The Bellfounder blood of the Clays on the side of the dam seems to supplement the dominant Messenger blood of the Hambletonian with its similar Bellfounder cross, giving a perfect trotting form.

"Clay Hambletonian" is thus, as to his breeding, in good company, and although never trained, his form and action indicate that he is capable of a rate of speed that would be creditable to the blood he represents. "Clay Hambletonian" is eight years old, stands 16 hands high, and weighs nearly 1,100 lbs. in his present condition. His color is a rich brown, with a star in his forehead, and one white hind foot. His proportions and general expression are well represented in the engraving; he has good legs and sound hoofs, and moves with a square, even gait. His sloping rumps and strong quarters—characteristic of his maternal blood—are seen to the best advantage when in motion.

## AMERICAN AGRICULTURIST.

NEW YORK, JUNE, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

So far as our observation and information extends the prospect for the various farm crops is good, and if average weather is given us until harvest time the farmer may expect a good return for his labor. Any trouble from "over production" is not to be feared as the foreign market is steady and will need all we can produce in the way of grains, meats, etc., to supply it. Emigration to the West is going on to an extent rarely before known, and it is reasonable to expect that there will be a good supply of labor for the present season; and a large area of new land taken up by the new comers and rapidly worked into productive farms.

**Corn.**—Frequent cultivation is necessary to the destruction of the weeds while they are young. A smoothing harrow may be used while the corn is small, to be followed by the cultivator and hoe, as the plants get larger. The double cultivator with a span of horses, is more economical than the single cultivator and a single horse, as it saves the labor of one man. One great advantage of the corn crop, is the opportunity furnished for thorough tillage, the beneficial influence of which will be felt throughout the whole rotation of crops. The labor expended upon the growing corn, should be charged in part against the crops that are to follow.

**Fodder Corn** may be sown in drills, 2½ to 3 feet apart, and at intervals of ten days, for several weeks to come. It is not well to sow the seed broadcast, as the plants, to do the best, need to be cultivated while young, and for this purpose, drills are necessary. The smaller varieties are preferable on account of superior fineness of the fodder. The notion that sweet corn is better for corn fodder than the ordinary field sorts, is without foundation. That the grain is sweeter in the former, does not indicate that the stalks are any better.

**Swedish Turnips** may be sown this month, in drills 30 inches apart. A plenty of seed should be sown, to insure an even stand of plants—2 lbs. per acre is not too much. The land should be well manured, and thoroughly prepared—a fine tilth is especially essential to success on old ground. Thin

the plants, when the second leaf appears, to at least 12 to 15 inches apart. Partial or total failure is, in many cases, to be attributed to defective thinning.

**Mowing Machines** have come to be an indispensable part of the machinery of the farm. It is a serious loss of time and money to get in any large crop of hay without using them. Scythes may be used around fence corners, trees, etc., but in open fields they must give place to the horse mowers, many kinds of which are so near perfection that it is hard to go astray in selecting one.

**Haying.**—Clover and Timothy should be cut when in full blossom; if allowed to get ripe, the quality of hay is not so good. By beginning early the work need not be hurried. Use the mower after the dew is off in the forenoon. Cut only as much as can be well eared for. It is often remarked that the average quality of hay is not so good as before the introduction of the mowing machines, from the temptation to cut the grass faster than it can be eared.

**Hay Tedders** are important implements in conjunction with the mower. Frequent stirring of the grass, to give the air access to all parts without burning the surface in the sun, is a great aid in making hay of the best quality. Grass cut in the forenoon, and well stirred with the tedder, may be put into cocks in the afternoon, when it will cure better than if spread over the surface of the meadow.

**Hay Caps** are excellent things to protect the hay from the damage that showers would otherwise do to the curing hay. They should be made of stout cotton, a yard or yard and a half square, provided with loops at the corners for fastening down with wooden pegs. If well cared for, a set of caps will last many years, and save several times their cost.

**Sheep Shearing.**—Washing sheep under the present system of buying wool, will perhaps be the prevailing practice. If care is taken to keep the sheep so that the wool will not be filled with dirt, it is better not to wash. Fleeces should be done up with care, nicely rolled and securely tied with light twine. When it is known that a farmer puts up his wool in neat shape without any tags, etc., he will obtain the highest price. Everywhere, but especially here, "honesty is the best policy."

**Ticks.**—Immediately after shearing, the ticks leave the sheep for the longer wool of the lambs. The lambs thus infested should be dipped in a decoction of tobacco stems, which will destroy the ticks. Several special dips are in the market.

**Potatoes.**—The Colorado Beetle must be kept in check by a free and judicious use of Paris Green, or the equally efficient and cheaper London Purple. The liquid method of application, using some sort of a sprinkler, is now most generally practised. It must be remembered that these substances are deadly poisons, to be handled with caution and stored in a secure place, or serious results may follow.

**Buckwheat** may be sown during this month, and may be made a profitable crop, especially upon newly cleaned ground where the mellowing effects of the crop are of importance. The Silver-Hull buckwheat is better than the common variety, the yield being greater, and the flour from it is whiter and of a finer quality than the ordinary sort.

**Poultry.**—Many chickens are carried off by hawks, rats, etc., unless safe coops are provided, which should be closed at night and not opened until the dew is off the grass in the morning.

**Cellars** should be ventilated at night and kept closely shut up and dark in the day time. The outer air highly charged with moisture, if allowed to enter the cellar in the day time will deposit much of its moisture upon the cold walls, and the cellar is made more damp instead of dryer by the day ventilation.

**Summer-Fallows.**—In rare cases it may be well to summer-fallow. The object is mainly to kill off weeds that have become plentiful and are otherwise difficult to destroy, especially on heavy clay soils. There are so many green crops that may be grown to advantage for cleaning the ground, that it seldom pays to keep a field idle for a whole season merely to rid it of weeds. If it is decided to summer-fallow it should be done with thoroughness.

that the greatest good may come from the expensive rest that is given to the fallowed land.

*Pigs* for early fall killing will need a regular and generous feeding of bran and meal slops. A quantity of milk, with a run in the grass, will do them good. A little forcing at the start pays well for pigs that are grown for the early market.

*Rubbing Posts.*—All who have the comfort of their animals at heart—and, we may add, desire to preserve their fences intact—should provide a few rubbing posts for the animals. The pleasure of seeing them used is pay enough, but there is more.

*Salt Boxes* are easily made and are very useful. A few boxes in the pasture will be a saving of the salt which is otherwise thrown upon the soil and largely lost. Long flat troughs may be used.

*A Horse Fork.*—In the hurry of haying, the saving which is made by using a horse fork will more than pay its cost in a few days. As a time and labor-saving machine, a horse fork should be used on every farm of any ordinary size.

*Working Horses.*—A thorough washing with clean water, not too cold, will greatly aid in keeping the working horses in a good condition; it removes the accumulated and dried sweat and dirt much better than dry rubbing. The harness should be kept clean and soft that it may not gall the animals. A little powdered aloes rubbed on with the oil will keep away any insects that are likely to infest the harness, and will do no injury to the horse.

*Calves* should have a good run of grass. The pushing of them without overdoing must be kept in mind. The first year's growth determines in a great measure what shall be the future of the animal.

### Notes on Orchard and Garden Work.

Whatever the earlier part of the season may have been, the first of June, take one year with another, finds the vegetation of the orchard and garden equally advanced. The work now is principally earing for the growing crops. The soil should be kept free from weeds and well stirred, especially if the weather is dry. The best time to kill weeds is while they are young, therefore the hoe, cultivator, and especially the rake, should be kept in motion. Clean culture is the only kind that pays, and it can be practised only by keeping ahead of the weeds.

### Orchard and Nursery.

In keeping the ground loose and free from weeds, horse-cultivation should be used as much as possible, care being taken to not bruise the bark, break the lower branches, or otherwise injure the trees. The ends of the whiffletrees should be thickly wound with cloth, or provided with leather pads, to prevent their doing damage to the trees.

*Orchards.*—With newly planted trees it will pay to give a little time in examining their condition. If they are loose or leaning to one side, a minute spent in pressing the soil about them with the foot will often save them. A mulching, if not already given to the young trees, should be provided before the long drowth. Almost any substance that will cover the soil and protect it from the sun will do.

*Labels* that are sent from the nursery are only to serve until the trees are planted. A permanent record of the position and kind of every tree in the orchard should be made before the nursery labels are lost or obliterated. A small plan can be made and carried in the pocket memorandum book. A plan of such a record was given in the "Notes" of last year (June 1879.) If the labels upon the trees are to be the only method of indicating the varieties, zinc ones cut in long triangular shape, 4 to 6 inches long, may be used. The name is written in lead pencil, and the narrow end coiled loosely around the limb. Such labels made and adjusted with care have been known to last for 25 years.

*Grafts* set this spring should be looked to; and if the bud or buds grow too vigorously, pinch back into shape; in fact a graft should be treated as if it were a young tree. Cut away all shoots that come upon the stock below the graft, that the nourishment may go to the graft. See that the branch-

es of the graft have plenty of room, and the growth is not interfered with by surrounding branches.

*Pruning.*—June is a good time for pruning. Larger limbs may be cut away now, covering all cuts with varnish, paint, or melted grafting wax.

*Thinning Fruit.*—The sooner this essential to the production of the best fruit is done the better. It is seldom overdone, and too frequently entirely neglected. Thinning increases the size and improves the quality of the fruit, and with young trees, just starting into bearing, it is a necessity.

*Baskets and Crates* for marketing should be provided, and let them be distinctly and neatly marked with the address of both shipper and consignee.

*Circulio.*—Begin as soon as the fruit is set to visit the trees in early morning; the sluggish insects may then be jarred from the trees and caught upon sheets opened beneath to catch them. The *Circulios* thus caught should be swept into the fire.

*Codling Moth.*—The "worms," after leaving the fruit, seek some hiding place to undergo their changes, and bands of cloth or hay, put upon the trunks of the trees, will catch many of them. The bands should be removed once in ten days, and the insects that have gathered beneath them killed.

*Tent Caterpillars* are best removed in the early morning while they are in their nests, and the dew glistening upon the web. A pole and swab may be used. The Wild Cherry is such a favorite of the Tent Caterpillar that it is hardly worth the while to keep any such harbors for it near the orchards.

*Pear Slugs* when so numerous as to do injury, may be destroyed by dusting the leaves with lime or ashes; even dry earth may be used with good effect.

*The Borers* of the peach and apple trees are to be looked to. When once in the tree there is no surface remedy. Heaping earth around the base of the tree, or using a close-fitting paper band will keep the female insect from depositing her eggs. For killing the worms the use of the knife and wire probe is the most effectual. Their whereabouts is known by the sawdust they make, and depression of the bark. Use the knife cautiously.

### The Fruit Garden.

*Currants and Gooseberries.*—A mulch should be applied early in the season; litter from the barn-yard, or "chip-dirt" from the wood-yard may be used. For the "worms" use White Hellebore, a tablespoonful of the dry powder to a pailful of water, the Hellebore being first scalded before going into the pail—apply with a syringe or Fountain Pump, repeating the application in a few days, and continue until the worms are all killed. If shoots start on the bushes where they are not wanted, they should be removed, thus saving much pruning in the fall, and the remaining growth is strengthened thereby. The fruit is frequently sold with greatest profit while green, especially is this the case with gooseberries. For making jelly pick the fruit when fully colored, but before it is "dead ripe."

*Raspberries.*—The green shoots that are growing now are the ones to bear the next year's fruit, the fruiting ones this season dying after the berries have ripened. When the growing shoots reach 4 feet they should be pinched off. Those not required for next year are to be treated as weeds. The old canes are to be cut away after fruiting.

*Blackberries* need much the same treatment as their near neighbors, the raspberries. The young canes are allowed a little longer growth, and should be pinched at 5 or 6 feet—all not needed are to be removed. Both the young and old canes should be kept upright by using stakes or trellises.

*Grape-vines* one-year old set this spring should grow only one shoot; let it be the strongest and best one put forth. Older vines recently set should not be allowed to bear this year. The young growing shoots of old vines should be tied up before they fall over or are broken by the winds; soft cotton twine or bast bark are the best for the purpose.

*Strawberries.*—A mulch of straw, cut hay, or leaves, should be applied before the fruit begins to ripen, that the berries may be kept from the soil. The picking and packing for market requires much

care and good judgment. All over-ripe berries should be excluded, as one such will be crushed and spoil the whole basket. The treatment of the bed after fruiting depends upon the method of cultivation. In any case the mulch is to be removed and the soil forked over. When the plants are kept in hills, the runners are to be cut as fast as they appear. In the alternate system they are allowed to take root between the rows, and the old plants are removed later in the season. Runners struck in small pots of soil will be ready to plant out in August, and will give a good crop next year. Layer the earliest and strongest runners for this purpose.

### Kitchen and Market Garden.

This is the time when the rake and the hoe count for so much in the success of the season's work. The weeds must be kept down, or much of the labor of preparation and planting is lost. It is observed that the rake is put before the hoe, and it should be so in the garden. A frequent use of a long and sharp-toothed steel-rake will save much hard hoeing, and at the same time keep the soil in a better condition for the young growing plants.

*Sowing for Succession* is a useful method of prolonging the season of many vegetables, and should be more generally practised. By sowing beans, peas, corn, etc., at intervals of a week or so, these valuable vegetables may be had through the season.

*Asparagus.*—After peas have come the plants should be allowed to grow up in order that the green foliage may accumulate food for next spring's early growth. A coating of manure may be added. Keep all large weeds out; the small ones will not grow after the ground is densely shaded by foliage.

*Beans.*—If the weather has been cold and backward, and injured the Limas, put in more at once. These and other pole beans need attention to make them all take to the poles. Sow Bush sorts, as the "Refugee" for succession and pickling.

*Beets and Carrots.*—Sow the main crop if not done already. Keep the weeds out and the soil loose. A succession of the "Egyptian" to use while young should be sown, using the thinnings for greens.

*Cabbage and Cauliflower* need frequent hoeing. Plants for late sorts in seed-beds should not be too crowded; they need weeding frequently, and if infested with the cabbage worm, sprinkle with ashes. For Notes on the Cabbage Worm see page 228.

*Cucumbers.*—For pickles, sow until the middle of the month. Drills are preferred, 5 to 7 feet apart. The ground should be well manured, by plowing furrows, and putting it in, and covering with an inch or so of soil. From 12 to 20 seeds per foot in the rows, gives a fair share for the striped bug, which is quite certain to give them a call. So soon as plants appear, dust with ashes or fine lime, and when well started, thin to three feet apart.

*Corn.*—Plant at frequent intervals. A top-dressing of guano is excellent. Hoe often.

*Celery.*—If the plants in the seed-bed get too large, cut off their tops, thus making them stocky.

*Egg Plants* are the last things to go out: they do but little before hot weather comes, and if put out too soon, get stunted by cold nights. Set out the plants in rich, warm soil. Abundance of manure and care are needed for good success.

*Lettuce.*—It is of little use to plant lettuce at this season, as it quickly runs up and goes to seed.

*Onions* need frequent weeding. For near market, half-grown onions put up in small bunches, are more profitable than when left to ripen.

*Parsnips and Salsify* should be thinned to 5 inches in the row, and hoed frequently, that the weeds may not get a start.

*Peas.*—Sow for succession, until the hot weather of summer comes, after which they do not pay.

*Peppers.*—Set out in a warm well-manured place.

*Rhubarb.*—The flower stalks should be kept cut off. Do not gather the leaf-stalks too late in the season, as it exhausts the plant.

*Squashes.*—The winter sorts should be planted now. Much care is needed to keep the young vines free from insects. Paris Green may be used; hand-picking takes time, but is effectual.

**Tomatoes** should always have some sort of support. A form of Trellis, with a treatment of the subject, is given on page 235. The large green worm that makes such quick destructive work with the vines, must be removed by hand-picking.

### Flower Garden and Lawn.

Planting is mostly over, and the care of the lawn, walks, and beds of plants, comprises most of the work. It is to be remembered that a small place neatly kept, is more satisfactory than a large neglected one. Do not attempt to do too much.

**The Lawn.**—In order to have a fine velvet turf, the mower must be frequently used; at least once a week. In the corners, and under trees where the mower cannot go, a sickle must be used. A neat lawn is the leading feature of a well-kept place.

**Walks and Drives** should be kept clear from weeds, by occasional surface hoeing and raking. Keep the center higher than the edges, and roll to make hard and smooth. Trim the margins.

**Bedding Plants** should be in their places. Ornamental designs entail much labor. The plants must be kept of a certain height by pinching and cutting, that the lines may be distinct, otherwise the intended effect of the design is lost.

**Climbers** need supports, and those not disposed to cling should be tied to the trellis or other object.

**Cannas** do best started in the greenhouse, and then planted in the open ground in settled weather.

**Spring Bulbs**, Hyacinths, Tulips, etc., should make a good growth of leaves, after which they may be taken up and put under cover until dry, then stored in a cool place.

**Annuals.**—Set out the tender sorts started under glass, and sow seeds for succession.

**Perennials.**—Cut away the flower clusters so soon as they fade, unless seed is desired from them.

### Greenhouse and Window Plants.

A stripping of the greenhouse at this season is not necessary. Many plants do better kept in, while others may be provided for a summer display of bloom. Gesnerias and their relatives are excellent for producing a fine show of in-door flowers, as are the showy Pelargoniums. A plenty of air, water, and shade from the hot sun will be necessary. Make all the repairs that the house needs.

**Window Boxes**, aside from their place at the window, may be used for decorating the porch or piazza. They must not be allowed to get dry. The plants in the windows with shade in the heat of the day and water may be kept looking fresh.

### Commercial Matters—Market Prices.

Money has been quite active for this season of the year; partly under the manipulation of speculators. Stocks have been less freely dealt in, and, especially toward the close, have been unsettled, and generally weaker.... Real Estate has shown increasing animation in the dealings, and a hardening tendency as to values.... Merchandise has attracted much less attention, notably in the Dry Goods, Boots and Shoes, Hardware, Drugs, Dyes, Fruit, Skins, and Leather. Hides ruled dull and heavy most of the month under review, but leave off more firmly, with a better demand noted. Naval Stores and Petroleum favored buyers, on a tame market.... Cotton declined sharply, and met with a comparatively slow sale in the option line, though in fair request for prompt delivery for export.... Wool tended to weakness, as to values, on more liberal offerings, and a very moderate call for supplies, especially from the manufacturing interest. The favorable advices from the public sales at London were of little advantage to holders.... Breadstuffs have been moderately active, and very variable as to price—Wheat and Corn falling severely under a pressure to realize; Flour also declining, while Rye, Oats, and Rye Flour were advanced. Toward the close, Wheat rallied sharply, influenced, in part, by a more urgent export inquiry, chiefly for winter grades for the Continent. Corn showed rather more steadiness. Oats left off heavily at reduced figures. Rye also yielded slightly. Supplies of Breadstuffs here had been cut down materially, prior to the arrivals from the Erie Canal, the first tow of boats from which source reached here on Thursday, May 6, adding considerably to the stock of Grain available. Extensive purchases of Corn have been made for shipment at the modified quotations. Spring Wheat Flour closed firmly; while Winter

Wheat product closed in favor of buyers. Unusual activity has been reported in Oats, through the month, largely on speculative account.... Provisions have been less freely dealt in, even in the option line, and have ruled lower, leaving off irregularly.

The visible supplies of Wheat—embracing the hoards at lake ports, in transit, and on the seaboard—at latest dates, embraced about 22,183,000 bushels,—of Corn, 12,155,500 bushels; of Rye, 545,000 bushels; of Barley, 1,351,000 bushels, and of Oats, 2,105,000 bushels, against on January 31, an aggregate of 30,100,000 bushels Wheat, 13,100,000 bushels Corn, 979,000 bushels Rye, 4,155,000 bushels Barley, and 3,080,000 bushels Oats. Ocean Grain freights have shown only a moderate degree of animation at much lower and irregular figures, but closed rather more steadily, including by steam to Liverpool, 4½¢. per bushel; to Bristol, by steam, to 5½¢. per bushel; to Antwerp, by steam, to 7½¢. per bushel, and by sail to Cork, for orders for vessels of average carrying capacity—say 3,000 to 4,000 qrs.—4s. 9d. @ 5s. per quarter of 480 lbs.

Prices for beesves the past five weeks were as follows:

WEEK ENDING	Range.	Larger Sales.
Apr. 12	7 @ 11 c.	8½ @ 9½ c.
Apr. 19	7½ @ 11 c.	9 @ 10 c.
Apr. 26	7 @ 11 c.	9 @ 10 c.
May 3	6 @ 10½ c.	9½ @ 10 c.
May 10	8½ @ 10½ c.	9 @ 10 c.

**Beesves.**—There has been a gradual increase in the receipts during the past five weeks. The week ending May 3, was remarkable in the Live Stock Trade in New York, the receipts of beesves rising to the unprecedented number of 17,151, or 2,911 more than were ever before received in a single week. The foreign shipments are very large. As the warm weather comes on, the market will be less satisfactory, and the prices somewhat lower. The quality of beef offered in the market, has been of good quality. A few poor steers brought only 8c; but most sold for 9@10; Choice lots to dress 56 pounds, from Kentucky, reached 11c.... **Milch Cows.**—There was also a gradual increase in the number of cows sold in the market, though the receipts were very limited. Market very quiet, and prices about the same as last month, namely, \$25 to \$40 per head for common cows, and \$45 to \$55, for those of prime order.... **Calves.**—The month opened with a good demand for live calves, which sold readily at an advanced price. Soon the receipts grew heavy, and the price fell gradually, until the close of the month. Buttermilk calves, and mixed lots, sold at 4@4½c., and common to choice Veals, at 4½@6c. Extra lots, brought \$6.25@6.35 per hundred pounds.... **Sheep and Lambs.**—There was a considerable increase in the number of sheep and lambs received in the New York market, for the month ending May 10. At the close, the market was quite unsatisfactory. Clipped sheep at 4½@5½c., with a few extra at 5½c., clipped yearlings 8@8½c., unshorn sheep 6½@7½c. Southern spring lambs brought 7½@8½c., State do., 7½@9c.... **Hogs.**—There has been a falling off in the receipts of hogs, with the market dull, at \$4.50 per hundred.

**The Horse Market** has been active all through the month. The demand for driving and coach animals is extraordinary, not only for use in cities at home, but for shipment to European markets. The prices for such animals range from \$300 to \$500 per head. Street car horses are selling at \$115@130, but at the close of this month the wants of the car companies will be largely supplied, and the market for these horses will weaken. The demand for fine carriage horses continues, and many more could be sold if they were in the market. Well trained stylish horses sell readily at \$300@350 per head.

#### Prices of Feed.

Cotton-seed meal	per ton	\$30.00
Linseed-cake meal	per ton	37.50
Middlings	per ton	24.00
Brans	per ton	23.00
Corn-meal	per ton	23.00

#### Prices of Fertilizers.

Nitrate of Potash (95 per cent.), per lb.	8 @ 8½c.
Sulphate of Potash (potash 44 per cent) per lb.	3½ @ 4 c.

Baugh's Manure for Tobacco and Grain, per ton	45.00
Walton, Whann & Co.'s Raw Bone Phosphate	40.00
Gypsum, Nova Scotia, ground, per ton	3.00

**A Crop of Frogs.**—Seth Green is of the belief that many farmers have fortunes in their present worth than worthless frog ponds. A little care in the cultivation of frogs, he thinks, will bring good returns in a large crop of food for family use, and also for the market.

# LAST CALL. Important Notice.

We invite special attention of all Readers to the following: For the reasons stated, we prepared a large and extensive list of Premiums. This was done early last year, at a period of *low prices*, and such favorable terms were obtained that the offers were very liberal. By reason of the special arrangements, all our readers can obtain useful, desirable articles and Books at very low rates *when taken as premiums*. Many thousands have already availed themselves of these advantages, and thousands of others *should do so*

## AT ONCE,

for the premium offers must close this month. The prices have advanced generally, and our contracts for obtaining them on the terms offered *end with this month (June)*.  No Premium Articles can be given which are not called for this month.

*But there is plenty of time before June 30, to fill up any premium lists already started, and to form new lists and secure any Premium desired.*

We hope that, on their own account, our readers generally will embrace this opportunity to get the Books and other articles available, while it is in our power to supply them on the liberal terms stated in our Premium List. (A copy of this list will be promptly mailed free to any one desiring it and sending for it by postal card.)

**BOOKS and LIBRARIES**, for one's own use, for a neighborhood, for Farmers' Clubs, etc., ought to be obtained *this month* through these premium offers. Ten or more persons forming a Club of Subscribers get not only this Journal for a year, but two-thirds of the subscription money back in their own selection from 847 **Good Books**.

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**Putting Plants to Sleep.**—In a recent lecture by the President of the British "Association for the Advancement of Science," Dr. Allman presented some experiments which show that the life of a plant, in at least one particular, is not so very different from that of an animal. A Sensitive Plant, the leaves of which, as many of our readers are aware, will "wilt," or fall down at the slightest touch, was confined under a bell-glass in which a sponge filled with ether had been placed. At the end of half an hour the plant was without "feeling"; all its leaves remaining extended, and showing no inclination to drop when touched. After being removed from the bell-glass, the plant soon regained its peculiar sensitive properties. Ether will also arrest the germination of seeds for a considerable time, without doing any injury to them.

**Agriculture in Pennsylvania.**—The Pennsylvania agriculturists have learned that "nothing succeeds like success." Last fall the Agricultural Society had a fair on the Centennial Grounds and in the "Main Building," and great was the success thereof. The Society's Treasury is astonished by a sensation of fullness, and its officers are making arrangements for a show this fall which promises to be a remarkable one. The Penn.

Horticultural Society will cooperate, and the refinements of agriculture in its widest sense, will be presented by them. But to keep the "boom" a going, the State Board of Agriculture will do some preliminary agitating this month. A Summer Meeting is to be held at Gettysburg on Wednesday the 9th, at 2 o'clock P. M. A large number of practical and interesting subjects will be presented by competent persons, and discussions are to follow. No limit is set to the duration of the meeting, but it is to be protracted until the business is disposed of. Nor are there any restrictions as to who may attend, "the public are invited to attend, as the discussions will be open to all." Information may be had of the Secretary of the Board, Thos. J. Edge, at Harrisburgh.

## What This Number Contains:

The Work of the Month, with numerous helpful hints about it for this hurried busy season, on pages 214 to 216, and the June Bee Notes, page 220.

A Special Feature of this paper is the **KEEPING OF ONE COW**, in Villages and Cities, as well as the Country—its convenience, healthfulness, comfort, and especially its economy. See example and notes about it, page 221, and the Prize Essay, page 230.

The most famous living Cow is pictured and described on page 225, and Dairying Hints on pages 226-7-8.

Noteworthy Herds of Cattle are talked about page 226. Cnrry Combs are numerous pictured and described, pages 228-9.

New Suggestions for Iron Fence Posts, that may perhaps prove of great general importance, with other talk "on the fence" question; pages 222-3.

A Commodious \$1,500 Country House, with plans and detailed specifications will meet the actual wants of many, and be suggestive to multitudes of others; page 224.

The Lawns about our houses have a new help to neatness in the "Lawn Sweeper," described on page 221.

The Balloon Humbug has "gone up," with sundry congeners; pages 218-19.

Weather Indications for Farmers generally, are to be helped forward by what the "Signal Service" is planning. See the new Farmers' "Weather Case," page 231.

Gardening in Public Institutions, by Peter Henderson; page 234.

For Rock-work Plants and others, see pages 233-4.

Hints and Helps for Farmers of sundry kinds; pages 226-7-8-9, and elsewhere.

Household Matters in quantity and variety, pages 236-7.

And for Boys and Girls there are sundry useful things, with pictures, pleasing, puzzling, etc., including the Farmer Boy's first sheep shearing, on pages 238, 239 & 240.

The "Basket Items" have no relation to a "waste basket," but are condensed information on a great variety of topics. See pp. 217-8-9, 220, and over on pp. 245-6-7.

**It is well** to always run one's eye over the advertising pages of this Journal, and see what is offered, by whom, etc., as a source of information. There are usually *new* and valuable implements, and other things worthy of attention, while no vile or quack medical nostrums are present to disgust the old, or deceive or allure the young. No man is admitted if there is not good reason for believing that he has both the *ability* and *intention* to do what his advertisement promises. The Editors have full veto power over every advertisement offered, and they exclude the advertisements of every party whom they would not themselves patronize, if wanting the articles offered.  When corresponding with any of these advertisers, sending for their circulars, catalogues, etc., it is well to inform them that you are a reader of this Journal. They will know what you expect (and what we expect) of them in the way of prompt and fair treatment.

**Hastening Prairie Sod Culture.**—The long time general practice has been to break up prairie sod in June and wait until the following year for it to rot. In "Editorial Notes by the Way," in *Minnesota*, published in the *American Agriculturist* last November, p.p. 457-8, instances were given of success in putting crops at once upon the newly broken prairie. Mr. Clarkson, in Nebraska, first turned a 3-inch sod and followed with another plow throwing an inch of the lower soil upon the sod; then harrowing it well he planted it immediately. Mr. Youmans and Mr. Nevins, in Marshall, Minn., broke the sod in May to July; in September they cut the sod with a disk-harrow or sod-cutter, and with a deeper plow turned them under, and got a much larger yield of spring wheat. A letter before us, from Jno. A. Owen, Esq., in Central Dakota, dated April 15, says: "We are using the Randall Wheat Harrow on sod broken last week, and sowing wheat at once. It puts the land in better condition than most of last year's breaking is in—cuts the sod all to pieces.

Costs about \$30. Tell all parties coming to the new prairies to get them by all means, or at least some wheel-harrow."—We suppose he means some sod-cutting harrow. It is certainly of great importance to new settlers to gain six months or a year in getting the prairies into crops. We invite further correspondence from those having experience in this matter.

**"Canoe and Camera."**—This is the title of one of the most entertaining and exquisitely illustrated books of the season, which the Orange Judd Co. have in press, and which will be ready when this reaches our readers. It is the result of recent, personal explorations by the author, Mr. Thomas Sedgwick Steele, being, as he terms it, "A Photographic Tour of Two Hundred Miles through the Maine Forests." The work is embellished with sixty illustrations of scenery and character, by well known artists, with new Maps of the State prepared expressly for this book, and the story is told in a most fascinating manner. It is one of the most delightful books of the year. Sent post-paid from this office on receipt of the price, \$1.50.

**Milk and Milking in Texas.**—It may seem strange to those who know of Texas as the great grazing State of the Union, to learn that nothing is more scarce there than milk, and that the owners of vast herds use butter brought from northern dairies. This was our experience 25 years ago, and we learn from recent correspondence that matters in this respect have not changed. A friend in Anderson Co., "W. B. W.," in reference to an article published some time ago on "Allowing Calves to Suck," writes, describing the manner in which the relations between cow and calf are managed in that State. It reminds us of what we have seen a hundred times, and is of interest as showing the very different management given to animals, according as we raise them entirely for their carcasses—beef—or for the products of their bodies when alive. Our correspondent writes: "Here in Texas, it is almost the universal custom amongst farmers to allow the calf to suck. When a calf is allowed to draw the milk from a young heifer, the mother has been taught a lesson which she will never forget, she has learned to hold the milk from the hand of the milker, and retain it for the calf, and will never afterwards give all her milk freely. It is amusing to see the process by which many Texas farmers manage to draw half a gallon or so of milk from a fresh cow. First, the calf has its turn, and takes a good pull, the cow in the meantime, with half-closed eyes, contentedly lets the milk down, after a while the calf is gently moved to one side, and fastened to the fence or held by a rope, by an assistant present for the purpose; the milker now takes his turn, and as cautiously as possible, draws down the milk. Presently a change takes place, the stream gets smaller and then suddenly stops. The cow, now wide awake, has turned her head and discovered that her offspring is not the milker, and no more milk will she give, except for the calf, which is now untied and allowed to have its turn again. The milk flows once more, and again slowly and cautiously the milker (with quart can in hand) takes his stand (for sitting is out of the question) on the opposite side from the calf, and they both pull together, the unwitting mother, not knowing who she is giving the milk to, calmly resigns herself to them both. [We have seen this performance varied by the Mexicans, where the milker is usually a woman. The calf begins to suck, and is pulled away by the milker, who takes its place, armed with a short club. The milk is received in a gourd or earthen dish, and the woman, between milking with one hand and holding the dish and clubbing the calf with the other, is very busy. Sometimes, if the calf is a strong one, milk is not the only thing that is upset. Ed.] This is the usual custom all over the country, the consequence of which is, that between the two the cow is rarely milked clean, and in three months she is dry altogether, or the trouble of getting a pint from her is so great that it is willingly resigned to the calf. I know a dairyman in this neighborhood who owns a lot of fine milk cows (as he terms them); he is now milking *twenty two*, and from that number takes *sixteen* gallons daily. One may visit ten farm houses, the owners of which keep from six to a dozen cows, and at eight out of the ten there cannot be found milk sufficient to whiten a cup of coffee. In this town of several thousand inhabitants, situated in a fine grazing county, it is almost impossible to buy country butter. During the winter months we use western altogether, at from 35 to 40 cts. per lb., while milk direct from the dairyman costs ten cents per quart in summer, and from 12½ to 15 in winter. One reason why such enormous prices prevail in the best grazing State of the Union, is the utter want of management with the calves, and the pernicious practice of allowing the cows to be milked by them."

**Damage by Insects.**—It is estimated that the amount of injury done by insects in the United States is \$200,000,000. The good they do is another question, to which no answer is given, and cannot be given in figures.

**The Size of Cows.**—The size of the cows a dairyman may desire for his herd, is somewhat a matter of fancy; but, other things being equal, when the cost of feeding, etc., is taken into consideration, the medium-sized cows are the most profitable. Cows are machines for making coarse food into that of a more concentrated and valuable form, and, like other machines, there is a size that does this work with the greatest ease, with the least waste, and therefore greatest profit.

**Do Thistles Enrich the Soil?**—It is stated that a good growth of thistles (Canada) leaves the soil richer than before. This is doubtless the truth, and the same may be said of any crop, provided it is not removed from the ground. This is merely the general way that soil is made rich in the organic elements that are so essential to the growth of profitable crops. But there is more than ordinary ability possessed by the thistle plant to enrich the soil. The roots penetrate to a great depth, and bring up large quantities of potash and other valuable constituents, and deposit them upon or near the surface, as their stems and leaves decay. Again, the mechanical action of a vigorous growth of thistles is to loosen, pulverize, and render the soil more accessible to the roots of other plants. Granting that the action of the thistle plant upon the soil is good, we must look at the other side of the question. What is the cost of this method of improvement? While the thistles hold possession no paying crop can be obtained. When useful plants are sown, they must be carefully tended, or the thistles will crowd them out. Lastly, the bringing up of valuable substances from the subsoil, can be as well done by plants that are themselves useful for food, as clover, etc., and no miserable weed afterwards left to infest the ground. The best that can be said of the thistle is that it is a miserable prickly pest, which, when allowed to have its way, loosens and enriches the upper soil.

**The Tenth United States Census** will be taken this month, and all persons should be ready to give prompt, full, and accurate answers to the questions presented by the Census taker. Any opposition to an open statement of the plain facts springs from an ignorance of the duties of the Officers detailed by the Government to gather the information, or a thoughtless disregard of the important objects for which the statistics are to be obtained. The value of the Census depends upon its fullness and accuracy, and to secure these ends it would be well for all persons to take a little time and get ready to answer the questions that *must* be asked. A rainy day may thus be employed with profit to all concerned.

**Roots.**—It is often the case that one has a small piece of ground that can be easily put into roots. An acre or so thus occupied will give excellent returns for the trouble of sowing and attention while growing. Sugar-beets may be sown now, and Ruta-bagas and Turnips a month or six weeks later. Where an early crop has been removed, or one failed, it may be useful to try a late crop of roots, maturing well before sowing.

**Clearing a Drain.**—If the drain is a short one, such as that which leads from the house to some spot not far distant it is often the quickest to take up the whole drain. Such drains, if stopped at any one place, are generally more or less filled all along and need a cleaning throughout. When the drain is a long one, and the locality of the stoppage is known, then open at, or above the point of obstruction, and after removing the impediment, the drain should be flooded with an abundance of water at that point. A force-pump is an excellent aid in this work, as it will give a pressure that will, in many cases, force all small obstructions from the drain.

**Science vs. Common Sense.**—Prof. Huxley hits the nail upon the head—and this is a thing that he is very apt to do—when he says: "Science is simply common sense at its best, that is, rigidly accurate in observation and merciless to fallacy in logic." When facts are seen as they really are, uncolored by prejudice, or obscured by ignorance, and are weighed in the balance of a cool sound judgment, we may say they are treated scientifically, and the man who can do this is scientific, as common sense, which he exercises intelligently. Such a man may be a mechanic, or a professor in a college; a farmer, or a lawyer. Let it be understood that science is not above the masses, because the masses have common sense, and it may be intelligently exercised.

**The Cabbage Flea.**—"H. G." Simmons, Mich. This is often very destructive in the seed-bed, and where it is known to abound, it is best to anticipate their coming, and just so soon as the young plants appear—when they first break through the soil, give them a dressing of air-slaked lime, or a mixture of ashes and plaster. Equal parts of unleached ashes, sifted to remove bits of coal, and land plaster, thoroughly mixed together, and kept in a dry place, is not only useful to keep off small insects, but in its application the soil is benefited. Mar-

ket Gardeners, near New York, use shell-lime for this purpose; it is exposed to the air until slaked, and then kept closely covered; where shell-lime can not be had, ordinary or stone-lime will answer; the other is only preferable because it makes a finer powder. Either of these sifted over the young plants, so as to cover them with the dust, is the most effective remedy thus far found for the little beetle, which, from its ability to jump, is popularly known as a "flea." Where but a few cabbage plants are required, they may be raised in boxes elevated 5 or 6 feet above the ground; this distance being too great for the leaping powers of the insect.

**Soil for Sugar Beets.**—The best Sugar-beet, when properly grown, should be conical, and with a single tap-root. To grow such beets the soil should be deep, mellow, free from stones, and abundantly rich. A deep sandy loam, with a plenty of vegetable matter, may be expected to produce, with clean culture, a profitable crop of Sugar-beets. A strong clay is not suitable, neither is a soil that is low and naturally wet and cold.

### Sundry Humbugs.

Sometimes a fraudulent scheme shows such an amount of ingenuity and knowledge of human nature, that we are tempted to overlook the rascality of the thing in our amazement at its audacity and 'entences. For example, handbills were recently largely circulated in New England, setting forth that there would be at a certain place on a given date a "Grand Mammoth Balloon Ascension." The bills before us give Bridgeport, Conn., as one place of this remarkable show; but the same bills have been circulated near other large places in New England, and the country for 20 miles around there well notified that the "ascension" would take place at these towns on given days. This handbill is something remarkable. On one side it proposes to have

#### 16 MAMMOTH BALLOONS IN THE AIR AT ONE TIME.

Then each of these balloons is to "carry two or more daring aeronauts, who will, when the balloons reach an altitude of 3,000 feet from the ground, LEAP OVERBOARD and float gently down to mother earth again by means of parachutes."—There is a picture with many balloons and their occupants going down in parachutes. It must be, as the bills say, a "Marvellous Spectacle," these chaps coming down, while there are "fifteen beautiful tricolored balloons soaring away towards the sun," and we may add in the words of the showman about the eagle—"the higher he flies the nigher he'll come to it."—But all this strikes us as a great waste of balloon material, for the aeronauts to leave their balloon, to go off to the sun and get burned up. But as we are told that the expenses are in part paid by a "subsidy allowed by the governments" of the different aeronauts, we suppose they can stand the loss. But this side of the hand-bill is nothing to the other side. There we have

"A MAGNIFICENT AND THRILLING BALLOON WEDDING away up among the clouds." This is all to be done in, or on, the "Sixteenth Balloon," which will represent nothing less than "Cupid's Bridal Chariot." This balloon holds "70,000 feet of gas," but that's a trifle to the amount used in inflating the description of the wedding. Its all very funny, and at the same time very wonderful. When the ceremony is over, the balloon is to be lowered, the bride to be presented with \$100 in gold, then "the wedding party will be started on their heavenly tour of bliss." Whether this "heavenly tour" means that they will be set adrift in the balloon is a matter about which we are left in doubt. When the bill calls these

#### "GRAND, SUBLIME, AND NOVEL ATTRACTIONS,"

we feel how weak the language is when it would express a "big thing." No wonder that people crowd by thousands to the towns where all these wonders are to be seen, all for nothing too. To be sure there is no Balloon Show at the time and place advertised, but people having come out for a holiday have some money to spend, and they fortunately find that there happens to be a circus at the place and they can go to that. It is all

#### A DODGE OF A TRAVELLING CIRCUS

to draw a crowd at the place and on the date where it is to be.—We should say, by the way, that the show is not Barnum's, as one of our correspondents quietly intimates; he has a way of presenting enough attractions inside of his tents to induce people to come to them, and would not at any rate resort to such a miserable deception. As this fraudulent bill is circulated solely in rural communi-

ties, we think it proper to warn our friends against being deceived by it. We have heard that the trick was played quite extensively in Texas and some others of the Southern States last year.... There are some schemes that are not really humbugs, but they allow

#### PEOPLE WHO WISH TO BE HUMBUGGED

to deceive themselves. Take, for example, certain silverware which is extensively advertised, four showy pieces for \$5. It takes not much figuring to show that here a caster, a cake-basket, and two other large pieces, are offered at \$1.25 each. No doubt that those who receive these articles will feel that they have been defrauded. We have seen the articles sent out by one establishment, and think they are as good as can be afforded for the money. But what does one want of plated casters and cake-baskets at \$1.25 each? The majority of people fail to consider that a thing offered for \$1.25 is not likely to be worth any more, and a cake-basket that has not probably near \$1.25 of actual silver on it is not worth much. Those who wish low-priced plated ware will have no difficulty in finding it, but it is far from being cheap.

#### RECIPE TO MAKE SOAP.

There are parties who sell recipes to make various things: recipes for the manufacture of Honey, for making Cheap—and dangerous—Illuminating Oil, or for making of somebody's Soap, are among the most common. One of our readers sends a recipe for soap, and asks what we think of it. In the first place the recipe, though it says so, is not for "making" soap, but for mixing it with other things. It starts with "any kind of bar soap," to which are added a solution of Caustic Soda, and Alum, Borax, and Benzine. These are melted and mixed together, and there is no "making" of soap about it. The addition of Soda and of Borax to soap in washing is sometimes practised, Alum is altogether useless, and the small quantity of Benzine directed can make no difference whether it is put in or left out. The humbug attached to the thing is the threat: "The Holder Hereof is Warned not to Divulge or Make Known any of the Ingredients Comprising this Soap,

#### UNDER PENALTY OF THE LAW."

We should like, just for the fun of the thing, to know *what* law? If a person paying a dollar for the recipe agrees that he will not give it to another, he is probably morally bound to keep his promise, but as to any penalties of the law, that is simply nonsense.... Inquiries begin to come about

#### "THE CO-OPERATIVE COMPANY OF CANADA,"

which proposes to sell all sorts of dry goods at very low prices, or as their circular says at "Fifty to One Hundred Per Cent Cheaper" than the same goods can be bought in stores. We as yet know nothing of this "Co-operative Company" beyond what its Circular states, and this reminds us strongly of a "Co-operative Store" at Chicago 8 or 10 years ago, that had the same name and made similar offers. In that case we could not see where the catch was, but feeling that where goods were continuously offered at much less than real value, there must be something wrong, we advised caution. That Chicago thing went on swimmingly for a while, gave people a sufficient number of good bargains to inspire confidence; those who bought once found the things so cheap that they would order again for themselves and their neighbors. One day the Co-operative Store ceased to co-operate, and the co-operators were not to be found, and a large number of persons are still waiting for the goods for which in their confidence they had sent their money. Whenever staple articles of trade are offered below their real value it is well to be on one's guard. Such things may be occasionally sold at a sacrifice, but it can not be done as a regular business. Besides if sold "100 per cent below" the price asked by others, what is that but offering to *give away* the goods? Our Arithmetic says "100 per cent" is the whole of a thing, and the only thing we can think of likely to be *sold* in that way is a piece of property "mortgaged" beyond its value, the purchaser being responsible and assuming the "bond." .... It is well

#### TO REMIND FARMERS

that this is a favorable season for the visits of the "Mowing-Machine Knife-Sharpener man." He will sell you one very cheap on condition that you will act as agent for their sale to your neighbors; you will please give him your address that the articles may come all right. In due time you will hear that the rich "note shaver" up the road, has been buying a piece of your paper, or be notified that the bank at the next town has discounted a note of yours. It may not be knife sharpeners, but whatever it may be, don't act as agent for travelling vendors, and don't sign your name for any purpose at all, not even your address, for any one unless you *know* him well.

#### MEDICAL MATTERS.

When we take up the pamphlet or circular of a new medicine we are sure that it will contain an account of how the stuff came about; the vendors of these preparations seem to think it necessary to publish some remark-

able tale. At one time it is a dying man who has just strength left to direct his son to the secret drawer that contains the recipe; at another the recipe is picked up on the sea shore, it having been placed in a bottle and thrown overboard from a sinking ship; or one has to go to Germany to learn about American plants, but the favorite way is to learn, as Eddie Eastman did, of the real wild original ab-original—and this turns up in no end of forms. Here is the story of Doct. Morse's

#### INDIAN ROOT PILLS,

and a very touching one it is. Doctor Morse had a father, and after spending large amounts in having him educated as a doctor, he sent his son off to get finished among the Injins, or as the pamphlet has it "to learn their successful manner of curing disease in nature's own way from plants and roots." Father Morse was sick and his son was still among the savages, he got sicker, he was thought to be dying and "every eye was bathed in tears," but "a rumbling noise was heard in the distance, like a mighty chariot winding its way hither, when all at once a fine span of horses [color not stated, but they were "fine"] before a beautiful coach [not behind it] stood before the door, out of which alighted a noble and elegant looking man."—The story is soon told.—This was Dr. Morse, the son; he just went to his carriage and took out some plants and roots that he had learned about "from the Red Men of the Forest," gave the stuff to Morse the father, who didn't die at all, but at the age of 95 rode 35 miles "in order to spend his birthday with the celebrated doctor, his son"—and if you don't believe it, there's a picture of the Senior Morse reading the Bible.

#### THE MORAL OF IT ALL IS.

If you are sick and want to be well, take these Indian Root Pills. When we wade through all this dreary stuff, with which the literature of quackery is filled, we are forced to the conclusion that such stuff is believed, for there is scarcely one of these various pills, syrups, and other nostrums, that does not give some such ridiculous story of its origin. All these stuffs, like their pills, start out with the statement, that all disease springs from "impurity of blood."—To get well, purify the blood—these pills purify the blood, take 'em and be well. Its all as plain as logic, and all an outrageous swindle upon credulous and ignorant people.... Inman is not alone

#### IN THE "FREE" RECIPE LINE.

One is sent out by a person in Rochester, which differs from Inman's recipe, in using some terms that are well known in medicine and pharmacy, but there are others that are not. To get the ingredients, one must go to a "botanic drug store," which are few and far between. It may be that all the constituents of the recipe may be had at such a shop, but the names given, are not such as are recognized in science, though they may have a meaning in "botanic drug stores." But the drugs are at any rate difficult to procure pure, and it all amounts to the same old story.—The advertiser has "made arrangements for their importation," he can always have some of the pure stuff, which can be had for a certain sum. We are told that the "purpose of making the remedy known, is not to realize money,"—of course not, for there is the talk about "substituting joy for sorrow,"—"defeating empiricism,"—"duty,"—"benefit my fellows,"—"went about doing good,"—but the stuff may be had for \$3. Is it possible that the writer of such goody goody talk, can suppose that his hypocritical cant is not all seen through? And yet, alas, it is not.

### The Liver Fluke, or "Sheep Rot."

Within the last few months there has been great destruction of life among the sheep of Great Britain, from the "Rot," which is the result of an unusual development of the liver parasite known as the "Flukes," (*Distoma hepaticum*). These animal parasites, which are something more than an inch long when full-grown, take up their abode in the passages leading to the liver, and when numerous, choke up the smaller channels, arrest the flow of bile, and otherwise derange the action of the liver. "The sheep suffer first from jaundice, which causes the skin and eyes to become yellow. At this stage, the sheep thrives and fattens rapidly, and the yellow color of the fat of many carcasses of mutton that are sold in the market is due to this bilious derangement. In a short time the sheep falls, the skin and eyes become white and bloodless, a watery tumor appears beneath the jaws, the abdomen swells from dropsy, the wool becomes harsh and easily parts from the skin, and after lingering some time, the sheep dies completely rotten, with every organ diseased." A pasture can become tainted with and communicate Rot to healthy sheep in the following way. The sheep infested with Flukes, pass the mature worms and their eggs, which lodge in the ground. The eggs soon hatch, and the young worms find a host in the mud snails common in low pastures. When these snails are swallowed by sheep—as they frequently are—the "fluke" reaches its most desired quarters, where it is most destructive. Sheep that are pastured on dry land, are ex-

empt from this trouble. When the Flukes are already in the sheep, a cure may be often found in the use of the following mixture: Ground Ginger, 2 oz., Saltpetre, 3 oz., Carbonate of Lime, 1 oz., Common Salt, 2 lbs., with 6 quarts of Water, and the same quantity of Spirits of Turpentine. A dose of two oz. of the mixture, given at intervals of four days, may effect a cure, if used in the earliest stages of the disease. When the Flukes are sufficiently numerous to produce the symptoms of Rot, the animal is past help and should be killed at once.

**Top-Dressing for Grass.**—"A. S. P." Flat-hush, L. I. An excellent artificial fertilizer for grass is Peruvian Guano; it contains Phosphoric Acid, Potash, and Nitrogen (in the form of Ammonia Salts), the three important constituents most frequently lacking when grass and other plants are not doing well. The guano costs about \$60 per ton, and may be used in doses of 150 to 200 pounds to the acre, at least once a year. Apply it now just before a shower, that the rain may take it at once to the roots of the plants and quick returns obtained.

**Ladders.**—A neighbor of ours wants to trim a vine that is running up and over his piazza, and has neglected it because there is no means at hand for getting up to the much needed work. This is but an illustration of the many cases in which, if a ladder was at hand, important work could and would be done, which for the lack of one is neglected. There is often more time spent in doing a piece of work, in a left-handed and imperfect way, than it would have taken to have first constructed the ladder and then done the job. In haying and harvesting now soon to be upon us, a ladder is often the one thing needful to get at some out of the way place, off of some mow, stack, or even load, and just before the rush, it would be proper to provide a ladder for the emergencies of the season. All can not make handsome ladders, but every one can construct a strong one that will serve his purpose. A straight pine pole sawed lengthwise through the center, and fastened together with "rounds" of oak or other hard-wood, makes a good ladder and is quickly done.

**Washing of Hill-Sides.**—One of the most successful methods of preventing serious damage from washing of cultivated hill-sides during heavy storms, is to terrace the hill by plowing. At short intervals two or three furrows of the soil are turned down hill, thus making a nearly level bank at short distances, as you pass down the slope. The last furrow makes a channel in which the downward water is caught, and may be carried off at one side of the hill—at any rate it will arrest the rapid downward flow, and give the water more time to soak into the soil. A hill-side, specially given to washing, should be put into grass after being terraced. With terracing and a firm sod as a covering, very little damage may be feared from gullies made by descending water.

**Old Rules in Old English.**—Gervaise Markham, in his book entitled, "Of the Hunting Horse," 1668, gives directions for "dressing" a horse as follows: "For the manner of his dressing after he is unclothed, you shall first curry him from the tips of the ear, to the setting on of his tail, all his whole body most entirely over with an iron comb, his legs under the knees and canbrels only excepted; then you shall dust him, then curry him again allover with a round brush of Bristles, then dust him the second time, then rub all the loose hairs away with your hands wet in clean water, and so rub till the horse be as dry as at first, then rub all his body and limbs over with an hair-cloth: Lastly, rub him over with a fine white linen rubber, then pick his eyes, nostrils, and feet very clean, and so cloath him, and stop him round with wisps, if you water within the house, otherwise saddle him after his body is wrapt about in a Woollen cloth, and so ride him forth to the water."

**The Test of an Animal.**—The blind devotion to the pedigree only, that prevailed a few years ago, has in great measure passed away, and intelligent breeders have come to understand that something more than a long line of recorded names is necessary to make an animal of value. A good pedigree is one that has the animals making it, of the very best quality, and that quality uniform and identical. Aside from the high standard of the ancestry, breeders look more to the animal itself—in other words, more to its own record of what it has done and can do, than to the fact that its parents, through a long line, have their names in the Herd-book.

**Stagger Bush.**—Our inquiry about "Stagger Weed" has brought a note from Mr. P. Sutton, Lackawanna Co., Pa., concerning the effects of the shrub popularly known as "Stagger-Bush." This, the *Andromeda Mariana*, is a very showy shrub, from 2 to 4 feet high, with pure white flowers, looking very like large Huckleberry blossoms. Unlike several of the *Andromedas*, it is deciduous, and when the new foliage comes out in early spring, it is greedily eaten by young cattle when first turned out. These, Mr. S. says, are made very drunk,

and sometimes die from the effects of the poison. The popular remedies are: bleeding, by slitting the ears and the tail; giving salt, or whiskey, and sometimes a half-pint of melted lard. The plant extends from Southern N. England to Florida, and sometimes is very abundant.

**Foot Rot, Scab, etc., in Sheep.**—When a fertilizer for plants or a remedy for diseases of animals is to be advertised in our columns, it is a "condition precedent" as the lawyers say, that we shall know exactly what the article is composed of. While we wish on general principles that there were no such things as secret preparations, yet they are often convenient, and it is frequently cheaper to those who would use such articles, for them to purchase them ready-prepared for use, than it would be for them to undertake to prepare them on a small scale themselves. Buchan's preparations for sheep can hardly be termed secret preparations, as the terms Cresylic Dip and Cresylic Ointment indicate at once that their active ingredient is Cresylic Acid—one of the coal-tar products, and whatever else is in them is merely for making easy the application of this. These preparations have been so long before the public that they may be regarded as standard articles, and they are successfully used for the various external parasites that infest sheep over a wide extent of country.

**"Kansas Millet."**—It is very difficult to keep the run of the common names of the grasses. T. Overton, Hamilton Co., Kans., sends a package of seed of a grass called in his locality, "Kansas Millet."—An inspection showed the seed to be that of *Panicum Crus-galli*, the Barn-Yard Grass. This is generally known as a weed, but in some localities it is cultivated as a hay crop. In Dec., 1875, we gave an account of its culture in Ill., and now we are glad to add the testimony of Mr. Overton, who says, "It is an excellent forage plant. I think it would be good for soiling."

**Beautiful Dried Fruit.**—Those who see the dried apples at the stores that have a tempting whiteness, being about as light colored as the fresh fruit, no doubt wonder how they can be dried so nicely. The fact is that such fruits are not only dried, but bleached. They are subjected to the same agent that is used to give hops a bright color, and to impart to straw hats their whiteness—viz.—sulphur. It will be recollected that we gave last year an account of the Zimmerman Fruit Dryer and its workings; not long ago the inventor wrote us that he had been experimenting in bleaching fruit, and sent us a sample of apples, quite the whitest we ever saw, bleached in his Dryer. Hereafter the Dryers will be sent out with the necessary change in the furnace to adapt it for bleaching, and directions for the operation will be given. Of course bleaching is only practicable with fruit in this or other closed Dryer, and could not be done with fruit in the open air. As the question is sure to be asked if the fruit is rendered any the less wholesome, we anticipate it and say—not in the least.

**A Needle is a Wonderful Thing,**—were not needles so common and so cheap we should think so. If one must have a needle and had only a har of steel, what work it would be to get a needle from it! Notwithstanding great improvement has been made, a large share of the work on a needle is done by hand, indeed several hands, for the operations from the wire to the perfect needle are numerous and each workman performs but one. If a simple needle is a wonder, a paper of needles is a bundle of wonders. Having occasion to use a particular needle for some microscopic work a short time ago we selected it from a package of needles as put up from the London Needle Co. Here were 100 ordinary needles of different sizes in papers, and 20 large kinds for darning and other uses, and the whole sold, sent post-paid, for the ridiculous price of 25c. We came near forgetting our microscopic work in view of the microscopic profit that must fall not only to those selling, but especially to those making the needles. Who would undertake to make 5 needle-eyes for a cent—letting alone making the rest of the needle.—It is all very wonderful—and as for quality—the microscope sustained the favorable report of the user of the needle.

**The Semi-Centennial Anniversary at Lima, N. Y.,** to be held June 6–10, will doubtless interest a good many of our readers who have enjoyed the educational advantages of the Seminary that has flourished there for fifty years past. Probably more than ten thousand young men and women have been taught in the Institution, many of whom have filled important stations of honor and usefulness. All Alumni and Students now living are invited to come together at the above date for a Grand Reunion, and we hope to be able to be present to greet some of those who were classmates nearly forty years ago, though of course but a small number of the four hundred old comrades are now living. For circulars giving particulars, address Rev. G. H. Bridgman, Principal, Lima, Livingston Co., N. Y.

## Bee Notes for June.

BY L. C. ROOT.

The system of management for the present month must be determined by the intentions of the bee-keeper. If box honey is desired, the hives should now be properly arranged upon the hives. If the Extractor is to be used, extra combs should be supplied for this purpose. If increase of swarms is the object, rather than surplus honey, preparations for additional swarms should be made.

In many locations, this is the month when natural swarms will issue most freely. In such sections, swarms may now be made artificially with most profit. There are many who allow swarms to issue naturally, but when unrestricted as to number, this is never desirable. Those who permit it should remember that it belongs to the benighted days of box hives and hrimstone pits. It would hardly be possible for us to give the different methods of artificial increase in the limits of these Notes. They are treated upon at length in every practical work on the subject, and no progressive bee-keeper can afford to do without at least one such good work.

"How much increase is desirable?"—This question is often asked. In answer, we would say that probably most inexperienced bee-keepers will reach the greatest success by placing boxes upon the hives, as soon as the bees will occupy them, and allowing one swarm to issue from such, as the season induces them to swarm, but never allow more than one. In this way a reasonable amount of increase may be secured, besides probably some surplus honey if the season be favorable. After the swarm issues, all of the queen cells should be removed from the combs, except one of the largest and most fully matured; or, what would be better, remove all, and introduce a laying queen. If the motto we have often recommended, viz., "Keep each hive supplied with a laying queen at all times," was observed, the gain of honey throughout the country would be doubled. If those bee-keepers who allow their bees to swarm without restraint would study the subject and see what they are losing, they would appreciate the value of this motto. It should be borne in mind, that when two or three swarms are allowed to issue, the old colony is without a queen from 20 to 25 days. At a low estimate, 1,000 bees would have matured each day from the eggs which, under favorable circumstances, a queen would have deposited during this time. The loss arising from the absence of a queen for 20 days would amount to 20,000 bees. A colony should not be left queenless for one day, as one can not afford the loss even of 1,000 bees. If much increase of swarms is desired, have laying queens in readiness, and when a colony is formed, which can best be done artificially, furnish it with a laying queen. Remove the boxes so soon as they are full, and supply their places with empty ones. All boxes and frames used should be supplied with starters, or full sized cards of comb foundation.

[Mr. Root very properly advises bee-keepers to have one good work on the subject, but is quite too modest to mention the fact that he has written such a work himself. The work is called "Quinby's New Bee-Keeping," and it embodies the teachings of Mr. Quinby, but the work is really by Mr. Root, and it gives in full detail all the operations of the Apiary according to the best modern practice.—Price, post-paid, \$1 50.—Eds.]

**Salt on Wheat.**—"J. P. G.," Columbus, Ky. Salt in moderate quantities will not injure wheat, but it will not benefit it nearly so much as is claimed by some. For instance, it will not so moisten the ground in dry weather, as to avoid the ill effects of a drouth, nor will it destroy injurious insects. Pure salt does not attract moisture; it might possibly destroy insects if a sufficiently large quantity were used, but as so much as 5 bushels per acre are rarely applied, its effect is not appreciable. It is supposed that the beneficial action of salt, is to make the straw stiff, and to better fill out the grain. Early in the spring is the season for applying salt to wheat or grass that the best results may be obtained.

**How Much Hay for a Horse.**—"B. F. H.," Fairfax, Ia. A horse will eat 20 lbs. of hay, and 6 quarts of grain a day, and a large horse will consume one-fourth more than that. Much depends on the vigor of the horse.

**The New Water Motor.**—"C. H. G.," Salt Lake City. We can give no more definite information about the water motor, nor of the address of the patentee, than we have already given. We believe the inventor is now in Europe, and is not giving any attention to his invention in this country. If any party made one for his own use, no penalty is attached to that, only a royalty could be exacted by the person holding the patent.

**Condition Powders or Medicine Food.**—When a food for animals, or a medicine for them, is advertised in our columns, it is proof that we know what the articles are. The "Condition Powders" to be given to horses and other animals, Egg food for poultry, con-

tain articles well known as tonics or laxatives, to regulate the bowels; they not only contain useful ingredients, but they do not contain anything which may not be given with safety. Were we to publish the recipes, very few would be at the trouble of getting the various seeds, roots, etc., and mixing to make the powder themselves. The same things ready prepared, and to be bought at a moderate price, will be purchased, and as they are ready for use, will be given, when otherwise they would not.

**The English Bee-Keepers.**—The season of 1879 in England has been one of general disappointment, and none have suffered worse than the bee-keepers. "And now that this wretched season ('Agricultural Gazette,' London) is coming to a close, those that really care for their bees must nubutton their pockets and buy food for them. It will take years for the country to recover the loss of hives of bees during the season of 1879, and bees must not be only very scarce, but also very valuable."—The English bee-keepers may have the consolation that the probabilities are entirely against their having another such an unfavorable year.

**Abortion in Ewes.**—"J. C. D.," Clinton, Conn. A ewe cannot be expected to produce a strong lamb, or a lamb at all, unless provided with nutritious food. "Herd's Grass," (Timothy), and salt hay, is not sufficient to properly nourish a breeding ewe, and enable her to produce a lamb. "Out of nothing, nothing comes." A pint of bran and oats, or less, a day for each ewe, would probably have prevented the loss of the lambs.

**The Post-Stamp Nonsense.**—Every now and then a letter comes to the effect that the writer has heard that a price has been offered for a million cancelled postage stamps, and asking us to give the address of the person making the offer. Several years ago we heard of a similar offer in England. Parties here seem to have the matter all straight except the name and address of the one who will pay the \$5, \$50, \$100, or whatever the sum, which varies greatly. The whole matter seems to us a piece of idle nonsense. Cancelled stamps are of no other possible use than to grind up to be worked into paper, and the mills can pay but a few cents per pound for this, or any other waste paper. But who makes the offer?

**Record for Dairy Cow.**—"W. K.," The new association for recording yields of Dairy Cows, is now in operation. The Secretary is L. S. Hardin, 309 Greenwich St., New York. The object of the Association, is the improvement of dairy stock, by encouraging the regular noting of the yields of butter and milk, and by furnishing an opportunity for recording these in permanent form, of which certificates may be given. Any cows or bulls from recorded cows, can be entered irrespective of breed or kind. Knowing by these records the value of each of his cows, an owner will be apt to keep only his best animals, and endeavor to improve his stock, and if this recording should become general, it would soon double the value of our dairy animals.

**Short Notes about Food.**—Two aged clergymen were chatting together, when one of them, referring to his long years of effective labor, said "he thanked God for having given him lungs of brass."—The other replied "he was thankful that his lungs were not made of brass, for they would have been worn out long ago."—Unlike other machines, our bodies keep renewing themselves as they wear away. We eat, say a piece of bread and of meat. After being mixed with saliva in the mouth, they go down into the grinding or dissolving mill, the stomach. From millions of little tubes all over its surface, a fluid is poured in called the gastric juice. By a sort of shaking up process this juice mixes with the food, dissolves as much of it as it can, and forms a sort of liquid which passes out of the right side of the stomach into a large tube called the *duodenum* (about 12 inches long). While the food is in the stomach some of it is absorbed through its coatings and goes into the blood, to be distributed through the body as described below. As the dissolved food enters the duodenum, the liver pours in a little bile, a green bitter fluid, and before it leaves this tube another kind of fluid, called the pancreatic juice, is also poured in. Now, the bread and meat (or other food), having been ground (masticated) in the mouth, dissolved (digested) in the stomach, and received its four distinct or different fluid additions—the saliva, the gastric juice, the bile, and the pancreatic juice, is a sort of milky fluid, and it passes into the upper end of the small intestine, a tube about 25 feet long in a full grown person, which coils back and forth across the abdomen down to its base, when it turns back and the whole coil passes under the stomach and down on the right side to its exit. A sort of worm-like (peristaltic) motion keeps pushing the food along. All over the inside surface of the long tube (or intestines) are millions of little open mouths of tubes that suck out some of the fluid food and carry it into the blood in the veins. This

blood, carrying the food particles, flows into the left side of the heart, where a sort of force-pump sends it through arteries into the lungs. There it comes in contact with the air breathed in. Other veins carry it back to the right side of the heart, where another force-pump drives it out through the arteries that branch out to every point of the living body—even into the bones, the finger nails, and the hairs. As this food-bearing blood passes along, every part of the body picks out some particles which are just suited to take the place of other used up particles that it has pushed out into the veins—the veins carry the dead matter, some to the lungs to go out in the breath, some to the bladder to go off in the urine, some to the skin surface to escape there. Thus it is that this wonderful machine is daily and hourly rebuilt out of food.... Different kinds of food serve different purposes. Carbonaceous food, as starch, sugar, etc., supply materials for making fat, and for uniting with air (its oxygen) that gets into the blood through the lungs to produce heat all through the body, just as carbon (coal) in the stove produces heat there. Other portions of food, as lean meat, gluten of bread, casein or curd of milk (called nitrogenous substances), go to build up and repair the muscles and tendons of the body—they are strength-giving foods. Some phosphates of lime in the food build up and replenish the waste of the bones.... Three practical hints: As above described, it takes from different fluids to prepare the food. If one swallows food without thoroughly chewing it to mix it with plenty of saliva in the mouth, an important ingredient is missing.—*Second.* If the food is not well ground in the mouth, it is longer and slower in dissolving in the stomach, and that organ is over-worked, and often becomes weak and diseased.—*Third.* If too much food goes down at a meal, the stomach is overloaded and can not properly prepare the food for the next process. Some of it goes into the intestines undigested (undissolved), through the intestine, producing irritation, inflammation, colic, and often diarrhoea, dysentery, or other disorders, often of a serious nature.

**Grimshaw on Saws,** is a handsome volume of about 160 large octavo pages, on heavy paper, with over 200 engravings, some of full page size, illustrating every possible style of saw, from the simplest to the most elaborate gang saws. Every detail about their manufacture and use, filing, setting, gumming, and repairing, is here given, and the book bears evidence of great thoroughness and completeness. Every patent relating to saws issued since 1790 is here given, as well as various useful tables. The author is Roht. Grimshaw, Ph. D., published by Claxton, Remsen & Haffelfinger, Philadelphia. Sent from this office for \$2.50 by mail.

**High Farming—What is It?**—To be brief, is it the growing of the best crops on the best soil under the best conditions; and finally the crop giving the best profit in return?—No. There are cases when a comparatively poor crop grown on a poor soil with little or no attention, may give the best returns—as is the case in the imperative extensive farming of a new country. High farming is when much capital is expended on little land for the production of large crops of great value. The production of beef on the plains may be as profitable as the growing of onions, but it is not high farming—it is the character of the culture the soil receives and not the profit, that determines whether farming is high or low. High farming is the profitable farming of old thickly settled countries, and the kind that we are tending to; but as yet it is by no means the best farming in all sections.

**The Farmers' Friend and Guide for 1880** is the title of a work of 200 pages about the size of the *American Agriculturist*, and filled with extracts from the agricultural papers in all parts of the country. Mr. Frank Harrison is the compiler, and at 50c. gives a great deal of excellent information for the money.

**A Beet Quarterly.**—"The Sugar Beet" is the title of a journal of 16 pages about the size of this, which has for its object the familiarizing of farmers with all that relates to Sugar Beets and their culture, and to give news items concerning the beet-sugar industry. The editors are Robert Grimshaw and L. S. Ware. Published every three months by Henry Carey Baird & Co., Philadelphia, at 50 cents a year.

**"Two Birds With One Stone."**—During a recent visit to a farmer friend, we noticed a leak in the tin pipe, through which he was pumping water for some cows and called the attention of our friend to the supposed waste, only to be informed that these holes were made on purpose to let some water run out into a large dish (which we had not observed) to furnish drink for the fowls. In this way, without any extra effort, both the cows and chickens were at the same time supplied with their necessary water.

(Basket Items continued on page 245.)

## Keeping One Cow.

MANY MORE FAMILIES SHOULD KEEP ONE—HOW IT PAYS—AN EXAMPLE.

A business man in New York, being troubled to get good milk for young children in his family, took our advice the latter part of the winter and, so to speak, went into the dairy business on his own account. The result will be instructive to tens of thousands of families in cities and villages. He had no pasture grounds, the only convenience being a roomy stall in a carriage barn, with opportunity for the cow to sun herself and take limited exercise in a small area, say 15 by 20 feet, at the side of the barn, and this was seldom used. The stall is kept clean and neat, with fresh straw litter, and the cow has remained in excellent health and vigor. Chewing her cud and manufacturing milk seem to give all the exercise needed. Her feed has been bale hay, cut in a small hay-cutter and mixed wet with corn meal, bran, and shorts, with some uncooked potato parings, cabbage leaves, left over rice, oatmeal, etc., from the kitchen.

A laborer is paid \$1 a week to milk and feed and brush her night and morning, and take care of the stable, and he is allowed any excess of milk she gives over 12 quarts a day. He prepares a mess for her noon feed, which is given by one of the boys at school when he comes home to lunch. The cow is a grade, probably 7th Jersey and 1/4 common blood. Her milk is rich, yields abundant cream, and as the owner's family say, "Is worth fully double any milk we ever got from the best milk dealers." One neighboring family gladly takes 6 quarts a day at 7 cents a quart, and would willingly pay much more if it were asked, and other families would be happy to get some of it at 10 cents a quart; but 6 quarts are kept for home use, and it is valued far above 7 cents a quart, and worth more than that amount in the saving of butter in cooking, making cake, puddings, etc. So it is a very low estimate to call the whole milk worth 7 cents a quart. No one could deprive our business friend or his family of their good, home produced milk, if it cost 10 or 12 cents a quart. An accurate account is kept of the feed; the man in charge orders at the feed store anything he desires for the cow, and it is all down on a "pass-book." Here are the figures for 100 days past:

### The Cow's Debit and Credit for 100 Days.

Dr.

850 lbs. bale Hay, at \$22 per ton	\$ 9 35
1,000 lbs. Corn Meal, at \$1.35 per 100 lbs.	13 50
400 lbs. Bran, at \$1.30 per 100 lbs.	5 20
200 lbs. Fine Feed, "Shorts," at \$1.55 per 100 lbs.	3 10
20 bundles of bedding Straw, at 10c.	2 00
Paid man for care and milking, \$1 per week.	14 30
Total expenses for 100 days	\$47 45

Cr.

1,200 Quarts of best milk (12 quarts per day), at 7c.	\$84 00
Money profit in 100 days	\$36 55

Or, to put it in another way, the 600 quarts sold actually brought in \$42 cash, and the entire 600 quarts used at home cost \$5.45. The cow cost, say \$65. The entire care, which was not paid in the surplus of milk above 12 quarts per day, is charged in the expenses above. The manure produced, if sold, would more than meet interest on cost of cow, and any depreciation in value by increasing age. Allow the above average to be kept up only 200 days in a year, and at the end of that time suppose the cow is sold for half price (\$32.50), and a fresh one substituted, there would still be a gain of \$40.60 for 200 days, or for a year a profit of \$74.10.

With good feed the \$65 cow will keep up a full supply of milk at least 26 weeks, and then be worth \$40 for continued milking and breeding. Sell her then and buy another fresh cow for \$65—a loss of \$50 a year. The above liberal allowance of \$47.45 for feed and care 100 days, amounts to \$173.19 a year. Adding the loss of \$50 for purchasing two fresh cows, makes the total annual expense \$223.19. This would make the supply of milk, 12 quarts a day (4,380 quarts), cost about 5 cents per quart, or not quite 51 cents for 10 quarts. This is not an exaggerated estimate for a \$65.00 cow, renewed every 26 weeks. The feed and care may be very much less than the above \$47.45 per 100 days, by saving all waste foods suitable for a cow, and by securing pasturage 7 or 8 months, and especially when a cow can be cared for by members of the family, thus saving

\$52.00 a year. Taking the country as a whole, probably \$50 will ordinarily buy a cow that will, on fair feed, average 10 to 12 quarts per day for the first six months after calving.

### Let Village Residents Keep Cows.

Every family on a farm of course keeps one or more cows, but we claim that the dwellers in villages, and very many in cities can, and should, each keep a cow. Good milk is the best of all food for young children, and it goes a great way in saving butter bills, and in the preparation of palatable nourishing food of many varieties. The above actual results show the economy of keeping one's own cow. Two to five families, according to size and numbers, can readily unite in having one cow kept, dividing the milk and expenses, and thus always have good, pure, rich milk at very moderate cost. The suitable refuse from the kitchens of three or four families would go a good way towards reducing the cost of purchased food. In rural villages summer pasturage can be obtained near at hand, which, with a daily feed of good meal will furnish a large supply of rich milk at a low cost. A boy can be secured at a small price to drive the cow to the pasture in the morning, and return her at night to the stable. A stable or stall can always be obtained at a trifling rent, and be kept clean. There are always plenty of gardeners or farmers who will gladly take the manure away so frequently as to prevent it being a nuisance, or disagreeable.

*We have no doubt that all residents of Villages, Manufacturing Towns, etc., can, by arrangements like the above, secure an abundant supply of pure, rich, fresh, healthful milk at less than three cents per quart, and at the same time add greatly to their home comforts, and save the health if not the lives of their little ones.*

### The One Cow Prize Essay.

Our recent offer of Prizes for Essays had in mind helping families, especially villagers, in the way of keeping their own cows. The proposals, as it happened, did not quite state what we really intended, and the Judges, in awarding the prizes, very properly decided in accordance with the terms of the offer. The first prize essay is given on page 220. One or more of the others will probably be given as we find space for them. Indeed, it will perhaps be best to incorporate several of the Essays in a small Manual, for the instruction of those who can and ought to keep one cow. The Essay (page 220) will be found usefully suggestive on this point, not only to village residents, but to many farmers also.

## A Lawn Sweeper.

In the Lawn Mowers of the English style there is a provision for taking up the grass as it is cut. American Mowers rarely have this handy attachment, for the reason that in our climate, when the grass is cut frequently, the short clippings shrivel up in a few hours, and are soon practically disposed of. In the moist climate of England the removal of the clippings is necessary, while with us they may usually be left without much disfiguring the lawn. Still, where the grass is thick, the clippings will often show

and, especially if the grass is a little long, neatness requires it to be raked up. Indeed, many who are particular about the condition of their lawn, have come to the conclusion that it is on the whole better to remove the clippings, thinking that the advantage claimed by allowing them to remain as mulch, does not offset the slovenly appearance

caused by the dry grass, and say that when the grass is properly thick, it affords sufficient shade for its own roots. In order to allow those who wish to do so, to take up the grass, the makers of the Philadelphia Lawn Mower have produced a Lawn Sweeper. This consists essentially of a rapidly revolving broom with a receptacle for holding the grass. The hand sweeper, as it appears when ready for use, is shown in figure 1, and figure 2 shows the various parts as they are separated ready for packing. The adjustments for bringing the brush to the proper height above the ground are simple and easily made, and the collected grass

Fig. 1.—THE LAWN SWEEPER, READY FOR USE.

is readily discharged. While the broom, made of split cane or rattan, is very durable, it is so arranged that repairs may be readily made; indeed all the parts are strong and serviceable, and the whole has the substantial air desirable in a machine for use rather than for show. Not only is the Sweeper useful for gathering the grass clippings, but by taking up rubbish of every kind, it will greatly aid in the neat keeping of the lawn. Any one who has raked over the grass in early spring is aware of the great amount of trash that accumulates; this can be taken off by the Sweeper with more ease and much more thoroughly than can be done by the rake. It is the practice with many to apply to the grass in fall a top-dressing of fine manure or compost; the remains of this dressing, after all the soluble parts have been washed out of it, can be most readily removed by the Sweeper, while for taking up fallen leaves in autumn it will do most efficient service. The Hand-mower, the one shown in the engraving, has a width of 34 inches. A horse machine is made with a sweeping breadth of 40 inches, and is so arranged that its contents may be dumped without stopping. In the introduction of the Lawn Sweeper as supplementary to their Lawn Mower, Messrs. Graham, Emlen & Passmore, have contributed greatly to the ease with which a lawn may be kept in the best possible condition. When a machine was received for trial we examined it sufficiently to see the working of its parts, and left it in the hands of the man who does the work

Fig. 2.—THE LAWN SWEEPER, SHOWING THE PARTS.

of caring for the lawn, without any special comment. In a day or two after the verdict was volunteered: "I want to say that that Lawn Sweeper is a very practical and useful machine."—Certainly the makers could have no more favorable comment than this from a practical man that their machine is both "practical and useful."

## Fencing and Fences.

It is entirely impracticable to answer the multitude of individual inquiries for specifications, cost of a particular kind and amount of fence, etc., etc. We do not deal in or supply any kind of fencing or materials. Nor can we report upon the various models and descriptions, often not very clear to be understood, that are submitted for an opinion. All received are examined as we have time, and answered if considered important. At least nine-tenths of all the plans, models, etc., of fence posts received, are too complicated and too expensive for general use in farm fencing. Posts that will cost 50 cents and upward, each, will not answer, nor will those requiring much digging and "planting." As the cost of iron and steel suddenly jumped up 100 per cent, we nearly dropped the hunt after metallic posts for a time, though they are very desirable on account of their permanence, their non-destructibility by fire on the prairies and elsewhere, and their easy setting and their firmness when well set. The price of iron having declined greatly during two months past, we resume the subject of

### Fence Posts.

#### Supporting Iron Posts.—A Suggestion that may Materially Aid in Solving the Metallic Post Question.

In the forms and plans for iron Fence posts, a great deal of ingenuity and expense is devoted to supporting the post firmly in the ground. A simple iron rod or bar, five-eighths to three-fourths inch in diameter, would suffice for most fence posts, if it would stand firmly in the soil. So would a wooden post 2½ inches in diameter, if of a tough, durable kind; and such posts can easily be driven, if sharpened. If the soil has any degree of compactness at 15 to 30 inches below the surface, the bottom of a very small post or rod will stand firmly enough; the trouble is at the surface. Unless the ground be very hard these small rods or posts will sway, and the various devices of collars, flanges, etc., are designed to prevent this. It occurs to us that a very simple method may be adopted thus: The places of the posts being marked out, take a sharp, narrow spade, flat, or curved like a tile-drain spade or scoop, cut out a surface hole, square or round, or triangular, 4 to 7 inches in diameter, and 5 to 10 inches deep, according to the compactness or looseness of the surface soil. If the soil is very loose,

Fig. 29. Fig. 30.

like a light prairie, this hole will be all the better if made by driving down with a sledge hammer or beetle, and withdrawing it, a piece of hard-wood (fig. 29 or fig. 30) with a somewhat blunt point, and large enough to make the hole of the size desired.

This will pack the earth firmly on all sides. Then in the center of these openings drive down the iron rod posts, or the small wooden ones, as deeply as may be needed, and complete the fence, with the spaces around the posts at the ground surface left open, as in figures 31.—A and B show round and

Fig. 31.

square openings made with a spade. C and D show the openings made by driving the blocks shown in figs. 29, 30; E and F show similar openings for small wooden posts. — Finally, fill these openings with a grouting, or mortar, made of hydraulic

cement and coarse sand, or sand and gravel, or even a sandy loam. It will speedily harden firmly into the soil and strongly support the post. A barrel of the hydraulic lime will suffice for a very large number of posts, and cost about one cent each—depending upon the amount required by the nature of soil, size of post, strength of fence desired, and the kind of gravel or sand or cobble stones available for mixing with the cement. With gravel or cobble stones a pint of cement may answer in a compact soil requiring only a small collar. If the average be a quart, the cost would be from 1 to 2 cents per post, allowing the cement to cost \$1.25 to \$2.50 per barrel, according to the locality and freight expense. The present N. Y. wholesale price of common Rosendale Cement is \$1.10 per barrel. The grouting can be mixed in a half-barrel or box on a wheelbarrow or wagon, and be rapidly shoveled in. It hardens in a brief time after mixing with water. Such collars will prevent rusting of iron or decay of wood at the ground surface where this is most likely to occur.—Probably a man could make the holes, drive the rods or posts, and put in the grouting of at least 100 posts in a single day's work.

If it be objected that posts thus set will heave by frost, we think this no more likely than when set in the soil unprotected. The cement will rise and sink with the rest of the soil. For iron rods, perhaps—and we only throw it out suggestively—the holes might be dug, wooden pins, the merest trifle larger than the rods, be set in, the concrete poured around, and the pins be drawn out just when the grouting sets, but is not hard enough to prevent their withdrawal. A smooth hole will thus be left to drive the rod through. If the cement stands half an inch above the surface to shed off water, and the soil be dry below, so that water will not collect and freeze the rod to it, the cement collar will rise and settle during freezing and thawing, without moving the rod.

Perhaps the above original suggestions may go a good way toward settling the metal fence post question.\* The cement can be used with any form of posts already devised. Round rods five-eighths inch in diameter weigh about one pound to the foot, and those three-fourths inch not quite 1½ lbs. per foot. At 3 cents per pound, a 6½ feet, ¾ inch, round bar, weighing 9½ lbs. will cost 28½ cents; cement say 1½ cents; total, 30 cents. For a five-eighths inch bar, 6½ feet long, 6½ lbs., 21 to 22 cents, cement included. Any form of bar may be used. A flat bar 6½ feet long, 1 inch wide, half-inch thick, weighs nearly 10 lbs., which, at 3 cents per pound, and 1 cent for cement, would cost 30 to 31 cents per post. If three-eighths inch thick, the weight will be about 7½ lbs., costing 24 cents, including 1½ cents for cement.

Very small Cedar or Locust posts, or of other tough durable wood, can usually be obtained cheaply—as the freight will be light—in many places at 6 or 8 cents each, and one or two cents worth of cement, used as above, will support them firmly. When iron falls to about 2 cents a pound, as it is likely to, we can get effective flat or round bar posts, cement included, for 15 to 20 cents each.

Figs. 32, 33.—R. H. Mong, of Delaware Co., Ind., sends us sketches of several forms of posts, from which we select the following two: Figure 32 shows a bar of round iron, ¾ or ¾ inch in diameter. The lower end is bent at right angles to form an imperfect ring, say 4 inches in diameter, which will lie flat upon the bottom of a hole, dug, or better bored with a post auger. A flat stone is laid upon this ring or base, and the earth packed in firmly, using small stones or gravel if accessible. A small bar, however strongly anchored at the bottom, will not be held firmly by the ordinary surface soil. Unless small stones are at hand to pack around it, hydraulic cement, described elsewhere, or some other support, will be necessary. The running wires can be attached to the upright bar by notches, filed or struck in with a cold chisel

\*N. B.—The above described methods seem to be so valuable, that we have applied for Letters Patent, to prevent any other parties from taking out patents, as we understand they would have power to do, if not forestalled—and thus prevent their use by our readers.

at the points where the wires pass, and fastening them with a binding wire twisted on. With the cement collar, probably ¾-inch rods will answer for ordinary fence, or better, ¾-inch. The size of the ring, and the depth of the base in the ground, will depend entirely upon the firmness of

Fig. 32.

Fig. 33.

the soil. In compact soil, with cement collar, one foot deep may answer. Allowing two feet for the ground portion, including the ring, and 4½ feet above ground, 6½ feet of bar will be needed. This will weigh, for ¾-inch diameter, about 9½ lbs., and for ¾-inch, about 6½ lbs. At 3 cents per lb., the ¾-inch rod, 6½ feet long, would cost about 23½ cents, and the ¾-inch for 20½ cents.... Figure 33 has the same underground base, but its upper end is bent at right angles to pass through an auger hole in a wooden piece 2 inches square or larger. It is fastened to the ground bar with two staples as shown. This is cheaper than the all iron post, but the wooden bar will of course decay in time, unless specially prepared, and it will not be fire-proof. (The artist erred in showing the wood part in the ground; it is to be kept entirely above the surface).

No. 34.—Herr Peter Werner, of Worthington,

No. 34.

Iowa, sends a sketch, and suggests that iron rods, sharpened at the lower end, may be bent readily into the form of a screw, as shown in M, or any shape desired, and worked into the soil by turning them, which may be done with a blacksmith's tongs, or large wrench. The upper end may be bent like O in the engraving, and an iron rod put in to turn them into the soil. The coils standing transversely will strongly support the portion above

ground. Such posts may be of round iron rods, M, or flattened bars, N, and these may be of any desired size, strength, and weight.

Nos. 35, 36.—C. D. Roberts of Sherman, Wyoming Territory, sends us a description of a fence considerably used with and without wire for Cattle Ranches, especially when small trees or poles are

Fig. 35.

plentiful, but heavier timber for posts and boards scarce. Mr. R. says, "it turns the wildest cattle, and holds the smallest lamb." It is also portable, and can be taken down and moved if desired. The base, fig. 35, is the split half of a larger pole or small log, of any desired length, in which two auger holes are bored near the middle, a little distance apart. Into these, two upright poles say 2 inches in diameter are set. The small poles for the running

fence are laid in between, the spaces left being of the thickness of the poles. The tops of the uprights are bound together with wire or pieces of old iron hoops. Flat stones or billets of wood placed under the base pieces will keep them from the ground and save decay. The distance apart of the base pieces will depend upon the length and strength of the poles available. No. 36 is the ar-

Fig. 36.

angement for wire, plain or barbed, having only one upright of durable wood, and somewhat stronger than when two are used. A brace piece is firmly fastened with heavy nails upon one side. Any kind of plain or barbed wire can be used on these stakes.

#### Experience with Barbed Wire.

FROM A MISSOURI CORRESPONDENT.

N. B. Shearer, Clinton Co., Mo., writes to the *American Agriculturist* that he is not interested in the manufacture or sale of barbed wire, and says: "... Four years ago I put up one wire above four boards for a neighbor, and one wire above five boards the following year. He told me a short time ago that no stock ever troubled those fences. Two years ago I put up forty rods for myself, joining my neighbor's pasture, using three slats at the bottom for hogs, and three wires above. He has a span of young mules that would jump an ordinary fence, and they tried those wires long enough for one of them to get an ear torn about an inch. Since then those mules are careful not to touch that fence. I was so well pleased with its needing no attention, that this spring I have put up 115 rods, using two planks at the bottom, and three wires above; I set my posts 16 feet apart, and drove a short stake at the center of the planks, leaving it high enough to reach the lower wire. I put the lower plank four inches above the ground, left a four inch crack between the planks, and put the lower wire five inches above the planks, with one foot openings between the wires. It makes a good fence. There is a good deal of wire used about here for the upper part of fences, but it is pretty well agreed that it needs planks or slats at the bottom. A good deal is built with three planks and two wires. Once in a while I hear of a steer or horse getting hurt, not because they don't see the wire, but because they are used to breaking over other fences, and they try the wire once, but never the second time. I don't think iron posts will be used here for some time, as White or Burr Oak posts can be had for 10 to 12 cts. each.

"My method of straining the wire is to fasten one end, and unroll the strand the whole length of the fence then, with a rail or pole, 10 or 12 feet long, I wind the wire around the pole, about two feet from one end, and with that end catch on to the post, and taking the other end walk around. By the time I get the wire fast to the posts, the unevenness of the ground makes it tant. Barbed wire is universally liked here, nearly every one making a new fence puts on some wire. Some would rather have three boards with two wires; others prefer two planks with three wires. It is pretty well agreed that it wants some wire to turn cattle."

DR. HORNE ON BARBED FENCES.

Dr. Wm. Horne, Veterinary Surgeon, Janesville, Wis., in a letter to the "Country Gentleman" writes: "Unquestionably the barbed wire fence has important qualities to recommend it. It is cheap in first cost, and quite serviceable. It is easily put up and easily kept good. It looks well and does not harbor vermin. This is all well enough, but there are more serious objections. It is unquestionably the most dangerous and cruel fence ever invented. As now put up, it is a murderous, treacherous snare, and inflicts much suffering upon our domestic animals. I am quite in a position to

know whereof I speak. I have seen numbers of young colts literally torn to pieces. One fine filly I saw with her throat cut, by being tangled in the barbed wire and struggling to get free. I have seen several with the joints literally sundered by this wire. I have seen a fine mare with her fore feet nearly sawed off. Many of these, and others, were my own patients. Some of them recovered fully, having only a few scars. Many of them were ruined for life. Sheep seem to be the next greatest sufferers from this fence. Many of them have been fearfully mangled and torn. Cows and swine do better. Cattle are much slower animals, and much tougher skinned; still I have seen some cattle badly torn and mangled. Pigs are very cunning, and not much liable to be seriously hurt. Lambs and calves suffer a good deal.

"In its present general construction, the barb wire fence comes under the law for the prevention of cruelty to animals, and it would be a simple matter to make an action lie, if properly managed.—The question is, whether we shall do away with this economical, useful fence, which is of so much value to the treeless farmer out of reach of the lumber market, or so far away as to preclude the possibility of wood fencing. I think not. Surely we can devise some modification of the evils following the use of this fence. I hope our intelligent stock-men will try and hit on some method which will do away with the objections to this useful fence."

Our first strong prejudice against Barbed-wire fences was gathered at Lincoln, Neb., and confirmed afterwards at Beloit, Wis., not far from Janesville. It was there that we first met with the Brinkerhoff steel strap, which, with the modified barbs we suggested several months ago, we still believe to be the most desirable fence. This is shown in No. 20 of our January number. But there seems to be some hitch in bringing it into the general market.

#### A Home-made Hay Rack.

It is now the time when everything should be put in order for the haying season, which, with all its hurry, will soon be upon us. Among other things, a good substantial Hay Rack, or "Hay-Rigging," as it is often called, if not already at hand, should be supplied; and this the farmer can do himself. The engraving is of one that the writer has used for years, and finds it in all respects satisfactory. In

CHEAP AND HANDY HAY RACK.

its construction two bed-pieces, A, A, are required, these run the whole length of the rack, about 16 feet, and rest upon the bolsters of the wagon. Oak scantling or plank may be used; but a lighter wood is better if made sufficiently large. In the one referred to, a white-wood log, 9 inches in diameter, was used; this was split in halves, the curved or sap-wood side being placed outward, with notches cut in it, to make a close fit with the stakes, and thus keep the rack from sliding. Three cross-pieces, B, B, of 3 by 3 scantling, and 8 feet long, are spiked upon the bed-pieces in notches made to receive them, and in the places shown in the engraving. Between the two rear cross-pieces, two heavy "hoops," C, C, pass over on a curve to keep the hay from falling upon the wheel below. The hoops are made from young hickory trees, 3 or 4 inches through, split in the middle, and bent to the proper shape. The ends are securely fastened in D-shaped holes in the cross-pieces. Inch boards about a foot in width are placed upon the middle cross-pieces, and form the "wings" of the rack. These boards are level. In the front, short standards rise from the ends of the bed-pieces, A, A, which are joined by the short cross-piece, B. The

short standards, D, carry the cross-piece, E, which is a foot or so above the bed-piece—the distance to be determined by the size of the front wheels. Upon this raised cross-piece, and running back in a slanting direction, are two boards, like those in the middle of the rack—but being raised in front they keep the hay from the wheels below them. To complete the rack, a "ladder" is put at the front; this consists of two stout pieces bolted to the inner sides of the ends of the bed-pieces, and approaching each other as they pass upward, and united by an occasional cross-bar. This ladder serves as a guide in loading, gives a place to fasten the reins, and is a means of getting off or on the load. Two pins 20 inches long are set upright in the rear corners of the rack, to keep the first forkfuls from sliding off. With a number of small bars, F, F, between the bed-pieces to hold the floor boards, the rack is ready to be put upon the wagon.

#### How Does the Water Enter a Tile-Drain?

It is generally supposed that the pores in drain-tiles admit the water; but they do not; if they did they would as capillary tubes transmit it very slowly. The ends of the tiles are not perfectly smooth, and when they are placed in as close contact as possible, do not make a water-tight joint. Let us suppose the conditions to be reversed, and we undertake to convey water to a distance in a pipe made of tiles laid as closely together as possible. Any one at all familiar with such matters will at once say that the water will leak out at the joints in passing through such a pipe for but a short distance. The manner in which the water in such a case would go out, allows us to readily understand how it

really goes in—it passes through the joints, and will enter as readily as it would leak out. Water always enters a tile or other drain from the bottom. The surface of the water, as it stands in the soil, is called the "water-table," as seen in the engraving. When during a rain water falls upon the surface, it at once soaks into the soil, passing by gravitation directly downward, until it reaches the standing water representing the water-table. The water in the soil then rises until the water-table cuts the line of the tiles, *leaking in* at the joints, when it begins to run off through the drain. If the water-table rises until it reaches the tops of the tiles, the drain will then run full, and the water will continue to run off by the drain until the water-table falls again to its bottom.

As to the amount of water which will enter at each joint, Gisborne, on the authority of Parkes, of high reputation as a draining engineer, says: "If an acre of land be intersected with parallel drains 12 yards apart, and if on that acre should fall the very unusual quantity of 1 inch of rain in 12 hours, in order that every drop of this rain may be discharged by the drains in forty-eight (48) hours from the commencement of the rain—and in a less period that quantity neither will, nor is it desirable that it should, filter through an agricultural soil—the interval between two pipes will be called upon to pass two-thirds of a table-spoonful of water per minute, and no more." Porous tiles are not desirable, as they can aid but little, if any, in the flow of water; they are not so durable, readily crumbling to pieces when exposed to frost, which in ordinary seasons reaches them at the outlets, and in extraordinarily cold spells may act upon them in the soil at the depth of two and a half or three feet. Tile-drains are often spoiled by leaving too open joints between the tiles, under the impression that the water can not otherwise get into the drain. In fact, the joints must be laid closely, otherwise the fine soil, or "silt," as it is termed, will wash in and in time so accumulate as to stop up the drain.

## A Country House, Costing \$1,500.

BY E. B. REED, ARCHT. BOST.

This design somewhat resembles the one given last month. The main part is raised to two full stories; the floor dimensions are reduced, and the whole is less expensive. It is believed to contain more than an average amount of accommodation for a dwelling of this cost, and to be very convenient.

Fig. 1.—FRONT ELEVATION OF COTTAGE.

ently arranged. .... **Exterior** (fig. 1).—The breadth of the front is 37 feet, and the extreme depth, 30 feet. The foundation shows 2½ feet above ground. The inclosing is of horizontal boarding for the first story, and shingles above, with a belt course of dentil work between. Of course the whole may be covered with the ordinary narrow clap-boards, or the "Novelty" siding. There are two pleasant Verandas, front and rear. The Bay Window projecting in front of the main part is square-sided, instead of the usual semi-octagonal, and has balcony finish above. .... **Cellar** (fig. 2).—Height of ceilings, 6½ feet; extends under the whole building. Four small windows are arranged to furnish light to all parts. The outside entrance is from the rear, and a stairway leads to the kitchen. .... **First Story** (fig. 3).—Height of ceiling, 10

Fig. 2.—PLAN OF THE CELLAR.

feet. The Hall is entered from both front and rear verandas, and doors lead to the parlor, sitting-room, and kitchen. The principal flight of stairs lead from this to the second story. The Parlor is square, with a front bay window or alcove, arched across on the inside. A plain window is placed at the center of one side. A mantel, not indicated in the cut, is put opposite the bay window. A door leads to the rear room, which may be used either as a sitting-room or a family bed-room. It has two

windows, an open fire-place, and a closet. [This room may be used as a Dining-room, though this would involve much carrying of dishes and food, and that too, across the main hall, unless a door be provided from the rear veranda to the sitting-room, and the veranda enclosed with glass for cold and stormy weather. The plan might be modified by cutting another room, for a library or bed-room, from the front of the kitchen, and let the kitchen

occupy a portion of the rear part now provided, and also the rear veranda, and part of the rear of the main hall.]—The Kitchen is really the pleasantest room in the house. In this the family spend very much of their in-door life together, and special efforts are made to render this apartment as cheerful as possible, by giving it a favorable position with good outside views, and where it shall be well sheltered from storms, and shaded from the direct rays of the sun. It is of fair size, with front, rear, and side windows, a large open fire-place, and a 5 by 6 feet pantry. A pump and sink (not shown on the plan) are placed between the fire-place and pantry, under the window. The stairs to the cellar is under the main flight. An outside door opens to the rear veranda. ....

**Second Story** (fig. 4).—Height of ceiling in the main house, 9 feet, and in the wing 4 feet at the sides, and following the roof to the full height of 8 feet. This story contains a hall, five rooms, and two closets. If desired, the rear wing room (6 by 14 ft.) may be furnished and used as a bath-room, with water pipes direct from the sink and pump below. .... **Construction**.—The foundations are of broken stone and mortar, 18 inches thick and 6½ feet high, 2½ feet of which show above ground, all neatly pointed where exposed to sight on the outside. The walls may be of brick where stone are not at hand, at a small additional cost, say \$15 to \$20. Chimneys are of brick, laid in the usual manner. The kitchen fire-place is arched to the height of 5 feet. Frame of sawed spruce, of sizes shown in the estimate below, all thoroughly framed and secured with hardwood pins. The entire sides of the frame-work are sheathed with rough selected boarding of even thickness. The siding is of 6-inch wide clear pine clap-boards to the height of the belt course. Above this course the sides are shingled [or otherwise, as above stated]. The Roofs and Verandas are shingle covered. The Valleys, Gutters, and Leaders are tinned. All exposed timber on the verandas is dressed and chamfered. Flooring for verandas of narrow white pine, and for the inside of wide spruce. Marble Shelves are put in each of the principal rooms. Plastering: white hard-finish on two coats of brown mortar. Painting: two coats inside and out of any desired shade. .... **Estimate**.—It being impracticable to follow the constantly changing prices, the items of cost are made at a uniform standard with those given in our more recent estimates.

94 yards excavation, at 25 cents a yard. .... \$ 23 50  
50 perches stone foundation, at \$2.75 per perch. .... 137 50  
4,000 Brick, in chimneys (laid), at \$12 per M. .... 48 00  
560 yards Plastering, at 25c. per yard. .... 140 00  
3,000 feet of Timber, at \$15 per 1,000, viz.: ..... 45 00

Carpenter's labor (not included above). .... 150 00  
Pump, Sink, and Incidentals. .... 108 40  
Total cost. .... \$1,500 00

**The Wire Age.**—We are told that the world has passed through a stone, brass, and iron age, etc.; and it now seems as if it had arrived at the wire age.

Fig. 3.—PLAN OF THE FIRST STORY.

In coming up the streets of a city, the first and the last thing to be seen, is a wire running—the mind only wonders where! Some one has aptly likened the interlacing wires in a city like New York, to the work of some giant spider, which has covered the streets and houses with a net-work of iron webs. But wires are not for city use alone. There are many times on the farm, when a piece of wire might prove of great service. There are other places than in a pig's nose, where, if a bit of wire was used, much trouble might be saved. Things will break, and there is nothing better for mending than wire. A piece of harness, or a part of the wagon, harrow, cultivator, etc., may come apart at just the wrong time, and nothing will so easily mend matters as a piece of wire, if it is at hand. We keep in our work-shop, a large spool (in fact two, for different sizes) of copper wire, which comes in play so often, that it is looked upon as one of the essential things in the outfit of the shop, and we commend it to every farmer, as one of the greatest of little conveniences. A small coil or spool of such wire, should be kept in the work-coat pocket; it will save a vast deal of going to the house for repairs, and be one way of saving

Fig. 4.—PLAN OF THE SECOND STORY.

money. One should never start on a journey, whether for several days, or only a few miles, without a coil of wire under the seat, or in some corner or part of the buggy or farm wagon. Thus provided, one has the means of repairing almost every minor damage to harness or vehicle. In the matter of wires, the country should not be out-done by the city. If it be "An age of wire," it should be so everywhere alike. .... Since the above was in type, an Oriole's or Hang-bird's nest is reported which the birds built near a mechanic's shop, and had securely fastened it to the branch of the tree by means of pieces of wire which were found by the thoughtful birds in the sweepings of the shop.

### The Jersey Belle of Scituate.

The most famous living butter cow to-day is "Jersey Belle of Scituate," the property of Mr. C. O. Ellms, of Scituate, Mass., dropped in 1871, and bred by Mr. E. D. Sohler. She is now nine years old, or will be on the 10th of next month (July). She is a beautiful cow of a rich-yellow-fawn color,

within a year or two, so that unless this wonderful cow excels her own record, she will be forced to accept a second or even a lower place.

Mr. Darling's "Eurotas" yielded within an ounce a day of the highest weekly yield of "Jersey Belle of Scituate" during one tested week last year. This year so far she has not done quite so well, but is making a high average. When the Ellms' cow be-

which was in the sixth generation. We have in the pedigree of this cow several instances of close inbreeding. Stated in the ordinary form, giving the dam's line, it is as follows: "Jersey Belle of Scituate," 7828, by "Victor," 3550; dam, "Jennie," 7827, by "Victor," 3585; g. dam, "Minnie," 7823, imported in 1860. "Jennie" and her famous daughter were therefore by the same sire, while "Vic-

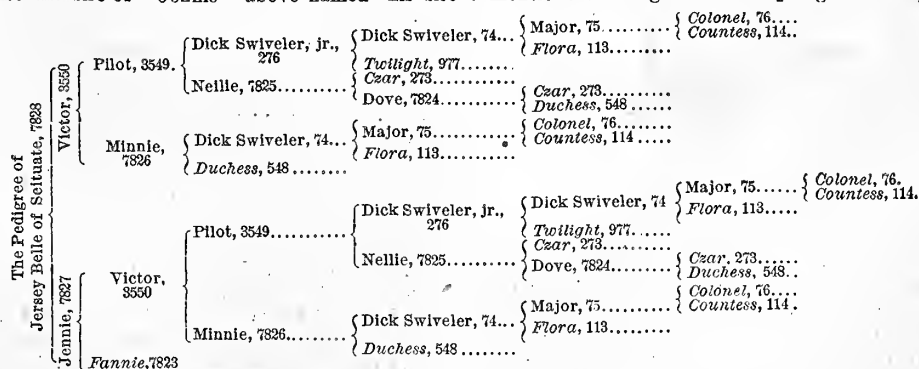

THE FAMOUS COW "JERSEY BELLE OF SCITUATE", 7828.

shading into a darker tint upon the head, diversified and mapped out with considerable white. She is above medium size, weighing 950 pounds when in her best condition, and really represents exactly such an animal in appearance, as well as characteristics, as may be, and frequently is, produced by the direct cross of the Guernsey and Jersey breeds. One of the best uses, by the way, to which inferior or unregistered animals of either Guernsey or Jersey blood can be put is to mingle their blood. Cross-breeds develop, with great uniformity, the excellencies of both of the parent breeds. In the case of "Jersey Belle of Scituate," it is a question, which probably can never meet with a solution—how much of her rare qualities does she, or does she not, owe to a remote Guernsey cross? Her butter is of as rich a color, and very much the texture and degree of firmness (or rather lack of firmness when compared with average Jersey butter) as the highest colored Guernsey product, and this high color is held throughout the winter. The engraving we give is a faithful copy of an admirable photograph.

The Ellms' cow we have said is to-day the most famous butter cow living. We mean to intimate that she holds that position only until some rival shall be fully attested to yield more than 22 pounds 13 ounces of butter in a week, or more than 705 pounds in a year. Some cow will surely do this

same famous she was unregistered, but believed to be perfectly pure. Many of her ancestry had been recorded in the American Jersey herd-book. Her dam, "Jennie," 7827, was then unregistered; her granddam, imported "Fannie," 7823, was unregistered. So were her sire, "Victor," 3550—who was also the sire of "Jennie" above named—his sire

tor's" sire, "Pilot," and dam, "Minnie," were very closely bred, one being by "Dick Swiveler," and the other by "Dick Swiveler, Jr.," besides, "Pilot's" dam, "Nellie," was by "Czar," and her dam, "Dove," also by "Czar," and out of imported "Duchess," 548, the dam of "Minnie" before mentioned. We give here the pedigree in full, im-

"Pilot," 3549, and dam, "Minnie," 7826. "Pilot's" dam also, "Nellie," 7825, and her dam, "Dove," 7824, were neither of them registered. To secure therefore the registration of this one cow, it was necessary to register seven other animals, one of

ported animals in *italic*. Breeders of cows in this country are putting in practice the lessons in close breeding thus forced upon them, and we mistake if within the next ten years greater progress will not be made in "butter breeding" than ever. There is, of

course, no evidence that "Jersey Belle of Seituete" has a drop of Guernsey blood in her veins. Yet we find in her, as in many cows upon the Island of Jersey, strong Guernsey characteristics. The fact being perfectly well known that Guernseys have frequently been, and may perhaps even now be, brought from the sister island to Jersey for breeding purposes, and it is fair to assume that this cow has, and is benefited by, some of their golden blood.

### A Handy Wool-Box.

The use of some contrivance in packing wool, that will make the fleece more presentable in shape, and safer to handle, is of importance, especially if the flock is large and the device is one that lessens the labor of doing up the wool. The Wool-box, as such aids are called, here presented, has been used by the writer so satisfactorily, and he can recommend it to others. It consists of a table made of three boards of sufficient length and width to allow of the spreading of the largest fleece. The boards are united by hinges, as shown in figure 1, so that the side ones may be turned up to form the box, as seen in figure 2. The width of the middle board

Fig. 1.—THE WOOL-BOX OPEN.

determines the length of the roll. At one end of the middle board is fixed an upright piece, broad at the bottom and thin at the top, the inner side of which is concave, to fit the curved surface of the finished roll. In the upper edge of this front piece three notches are sawed, in which are held as many ends of balls of wool twine. Each twine runs from this attachment along the bottom of the box, to holes in the bottom board, near its middle. The balls are held in a basket below the table. A compound pressure-strap is made of four heavy straps of leather—we used old tugs split in two—and tacked to the bottom board near the base of the front standard, and united at the opposite end by a small rod of iron carrying a small hook, the latter fastening into a hole in the bottom board. The straps are a short distance apart, and the twines are below the open spaces. There is a lever fastened at the bottom of the table and running out in front into an eye, to which the hook of the pressure-strap is fastened when the fleece is to be pressed.

Figure 2 shows the method of using this Wool-box. After the wool has been brought into shape by the hands, and the sides of the table turned up

Fig. 2.—THE BOX CLOSED.

perpendicularly and secured by pins, the wool is pressed into a loose roll, when the pressure-strap is brought over the fleece and the hook fastened into the eye of the raised lever. The lever is pushed down with the foot, and the strings brought up and tied between the straps, when the work is done. From experience we know that this Box is a very handy one, and with it a person can do up the fleeces much faster and better than when done simply by hand. With wool as with other products of the farm, the highest price is obtained, other

things being equal, when it looks the best, and this device, which any one can make and use, is a labor-saving one that turns out good, closely packed fleeces of pleasing appearance in the market.

### Among the Farmers.—No. 53.

BY ONE OF THEM.

My recent wanderings have taken me among the herds of five or six good breeders, and I have been strongly impressed by one fact, which is not by any means a new one, viz., that

#### The Bull is Half the Herd.

I went down to Oceanic, N. J., on the Shrewsbury River, to see Dr. Ehrick Parmly's herd of Jerseys. He inherits a fine old place. I don't know its history, but presume it was built by some old sea captain, grown rich upon the sea, and so loving the rolling waves, he had seen so much, that he wanted to live ever within the sound of their roar.

#### The Jerseys.

There have been several good Jersey breeders in this vicinity, and prominent among them was Robt. L. Maitland, who imported some of the best blood that ever came into the country. Charles Carow also imported some animals which proved very good. Dr. Van Buren, and E. Delafield Smith, have each had excellent herds, and brought famous blood into the vicinity. Dr. Parmly's herd was simply a useful one, there were no "fancy" cows in it; no very beautiful ones. A breeder would call them "good plain things." Two years ago, he exercised most excellent judgment, in placing at the head of his herd, "Prince of Seituete." His dam is "Belle of Seituete," and his grand dam "Jersey Belle of Seituete," the most famous Jersey cow in the world. She was famous then, but not so renowned as now.

The bull is a beauty. His color is yellowish fawn running into gray, with considerable white. A beautiful head, full eye, neat incurved horns, but like daggers. His back is level, his body deep, his flank very deep, his neck light, tail fine, loin broad, and rump bones wide apart; great length from hips to rump, and from rump to hocks. He is low set and fine limbed, with a hide as soft and silky to appearance, as that of a well groomed horse. But I did not handle him. He was loose in the yard with the cows, and clearly "monarch of all he surveyed," when strangers were about and took liberties. He had a playful way with him, which did not seem vicious, yet I would not like to offer myself as a plaything for him. I think I would rather have had him play with Mr. John D. Wing, who was present, or with almost anybody else. There is a beautiful

#### Flock of Yearlings,

daughters of "Prince of Seituete"; last summer's calves coming a year old. These look as much alike as their dams are dissimilar; as to color, their hues vary. They are bright, upcaded, gentle things of excellent form and promise in every respect, generally large teated, with good escutcheons, and though deep-bodied, straight, fair limbed, graceful, and deer-like, and withal of high quality.

The Doctor may well be proud of his bull and of his get, for now he has the foundation laid for a superior breed, and in this case I certainly would say that the bull is sure to prove three-quarters of the herd. Not that the cows are not good. They are, but they lack style, and breeding, and that show of "quality," which, as it is present or wanting, is equally marked in beasts as in mankind.

A few days after, I had an errand which took me to Patterson, Putnam Co., N. Y., where I saw the

#### Herd of Mr. R. C. Paterson.

This was selected with care, and comparatively high prices were paid. The cows are largely of the Bronx and Bashan family, in fact, this is the only herd I know of where this blood preponderates. They are generally above medium sized, with large bodies, large udders and teats, and are very large milkers for Jerseys. Many are solid colored, and they have a uniform look, which is desirable in any herd. The farm is in one of the best milk-producing sections of the State—the head of the Valley of the Croton River—and Mr. Paterson's ambition

has been, of course, not to have his Jerseys esteemed as poor milkers by his neighbors—to whom milk (quantity) is everything. He has so far succeeded that he openly challenges any of the neighboring herds to show as good an average. While as to quality, without making any intentional tests, he finds that his record of butter actually made and weighed, averages about 250 pounds a year for each cow. His bull is "Mopans," now an old fellow, but of excellent form, and of that solid dark brown, shading into gray, with the darker shades nearly black, which is a favorite color with many. He is of an excellent milking strain, and his calves are much like him, solid, with black points, the darker colors predominating. Here I would certainly say that "the bull is half the herd." There is a very fair blending of the characteristics of sire and dam, so that a casual observer would hardly venture to give the preponderance to either parent.

Not very far from Mr. Paterson's place are the

#### Norfolk Red Polled Cattle

of Mr. G. F. Taber. There are about 40 of them, and though there is so great a similarity in all the animals of the breed, yet any one can see that, while there are marked differences among the imported cows, some being low set, broad and deep; others are much taller, and differing more or less in all their points when examined critically. Among the young stock no such divergence from the normal standard exists, and this to a great extent I would attribute to their sire. It is an old idea that the young animal as a rule receives from its sire, as regards physique, *external character*, and from the dam those qualities which more directly affect its life, and hence are called *vital characteristics*. If this be true, it is not to be wondered at that in looks—that is in externals, a good bull would mark his offspring so as to occasion a strong similarity. But it is supposed that the nervous organization is derived especially from the sire. Hence docility, gentleness, intelligence, confidence in his friends, are traits, which, existing in the bull, one would expect to see reflected in his get.

Mr. Taber was absent when we arrived, and having permission to examine the Norfolks, we did so, and found the old bull, so quiet and peaceable as to permit himself to be handled by entire strangers, while the younger one—a three-year old—was throughout vicious, yet timorous and nervous to a high degree. Their calves possessed the same traits, though treated identically alike.

I don't know how familiar the readers of the *American Agriculturist* are with this admirable breed, and so I give a brief description. Suppose heavy low set Ayrshires to have the color of Devons, uniformly, that is, mahogany red, or between the red of cherry wood and old mahogany, with big udders, as they (the Ayrshires) usually have, but with big teats, which the Ayrshires usually have not, and with better beef points—that is, deeper in the flank and brisket, fuller in crops and loin, and better let down in the twist,—and withal hornless, and a very fair idea may be had of the Improved Norfolks. They are excellent milkers, have large calves, which are easily fattened, and they have proved, with Mr. Taber, very hardy and healthy. He sells his milk, so that I do not know what the herd would do put to the butter tests. If they resemble the Devons in this, as they do in so many other points, they will be found to excel. It was a fine herd.

A few days later, and last in order of time, I had the pleasure of visiting for a short time the

#### Jersey Herd of Mr. Horatio Parke Kretchmar.

Mr. Kretchmar is a nephew of that excellent breeder, the late Horatio S. Parke, whose sudden death a year ago cast a deep gloom upon a large circle of friends. He has much of his uncle's love for cattle, and enthusiasm in breeding them, and as the honored name, the tastes, and the fine herd are now his, we may look with confidence to its continuance as one of the best herds in the country.

Early in the Centennial year I went out to the Channel Islands to buy cattle, and had a commission from Mr. Parke to buy the best bull I could—answering certain conditions, which indeed were so accurately stated, that he may fairly be said to have selected the bull and not I. We were, however, so

well in accord in our views, and so thoroughly understood one another that knowing so exactly what he wanted, I was under no temptation to exercise the right of private judgment. Happily I found an animal—a yearling—so near the standard that I could only hope that he would not grow away from it before Mr. Parke had the opportunity to confirm my judgment, which in time he did. It was a pleasure the other day to see the mature bull, the sire of as beautiful and uniform a lot of young things as one ever sees in a herd, more than fulfilling in his full age the promise of his youth.

Mr. Kretchmar has one famous cow in his herd,

#### "Annie Page,"

She is by a son of "Alpeha" (the last calf of his famous dam,) who stood for several years at the head of Mr. Parke's herd. She was a beautiful heifer, and at eleven months old was found with a fully developed udder distended with milk—and from that time, although she did not calve until ten months after, was regularly milked with the rest of the herd. She developed to be a cow of fully medium size—a deep milker, and extraordinary butter maker, and although tested by Mr. Parke, no memorandums of recent tests can now be found. She will probably be tested again this year. Her daughter, "Annie Gold-dust," by "Jersey Gold-dust," dropped a beautiful heifer calf by the same sire, the day that I made my visit—double "Gold-dust" and "Alpeha"—pretty good blood we should say!

### Another Flood Gate.

Hard rains will come, and small streams and open ditches that are almost dry one day, may be rushing torrents the next. This makes it a matter of importance to provide a suitable and safe flood gate, at all those places where the farm fences cross such streams or ditches—gates that are easy of construction, permanent, and above all, self-adjusting. Several flood gates have been presented to our readers from time to time, but none like the one shown in the accompanying engraving. It consists of a stout piece of timber—a straight pole will answer—which fits into round holes in the fence posts on each side of the ditch. To this bar, which turns readily in the posts that hold it, the gate, or the length of fence, is securely fastened with heavy spikes, or better still, with bolts. On the lower portion of the gate, an addition of short boards, cut to fit the ditch, may be made as shown in the engraving. The whole gate thus constructed, turns readily upon the horizontal bar, the bottom

A SWINGING FLOOD GATE.

swinging out with the water and allowing it to pass, but returning to its former position, so soon as the water subsides. In making this gate, it should be borne in mind that the part below the turning bar, should be a considerable heavier than that above, so that small stock will not try to push their way through; that is, it is to swing only by the application of a strong pressure at the lowest part, as is the case with a rising, rushing stream.

**Judging by the Outside.**—The surface of an animal can be taken as an index of its health, and feeding powers, with considerable accuracy. An animal that has a long and soft coat of hair, with the skin soft and elastic, though with noticeable

firmness when grasped by the finger, is generally one that is healthy, and has a good constitution, and sufficient capacity as a feeder. On the other hand, the harsh, coarse coat, and hard unyielding skin, are found upon slow feeders, and inferior animals. A good judge of stock can pretty well satisfy himself of the quality and value of an animal, by the looks and feeling of the surface.

### A Home-made Field Roller.

There are few more useful farm implements than the roller—and there are few, if any, the use of which is more generally neglected. It is one of those implements that may be had with very little

Fig. 1.—A CHEAP FARM ROLLER.

outlay, as it can be made by any farmer who can use ordinary tools. Every field of winter wheat ought to be rolled in the spring so that the plants that the frosts have heaved from the ground may be pressed back into the soil again, and a smooth surface given to the field for the reaper that, in a few months, is to follow. There is no meadow, especially if it is to be mowed with a close cutting machine, but that will be benefited by the passage of a roller over its surface. But besides its value

Fig. 2.—COVER FOR ROLLER.

upon the winter crops and meadows, the roller has a more important use upon the newly plowed field, in the breaking down of such clods and lumps that the harrow often fails to touch. Upon a light soil, where there are no clods, the roller is of great utility in compressing the fine particles of earth, thus making it sufficiently compact for the crop to thrive. The use of the roller after sowing seeds of all kinds may often make the difference between the success of a crop and its failure. By bringing the earth in close contact, every good seed will germinate, while without the pressure given by the roller, a large share of the seeds may fail for want of sufficient moisture for germination; or if they do start the germ dries and is killed. Gardeners are well aware of this fact, and in their operations use rollers of a size suited to their work, or beat down the earth with the back of a spade.

That roller which will most effectually break lumps and do its other work at the least expense, is of course the best; but of the many kinds now in use it is difficult to decide which is the best for all cases. The cheapest, so far as first outlay is concerned, is one made from a log—and the oldest.

Those in which cement is used for the roller, when well made, are lasting and satisfactory, and not expensive. The one which the writer has used for a number of years, was made upon the farm, and entirely by the farmer, except the small amount of iron work which was furnished by the nearest blacksmith at a moderate cost. It is a double roller, of the style shown in figure 1, that is, consisting of two rollers equal in all respects, joined end to end. A roller thus divided is much easier to turn upon the land, as one half turns forward and the other backward in the movement. The "barrel" portion, as the revolving part is called, is about 4 feet long, 3 feet in diameter and consists of two end pieces or "heads" of inch oak, to which the "staves" of narrow 1½-inch oak stuff are spiked with heavy nails. The axle, which passes through the center of the rollers, is

a round bar of 1½-inch iron and is secured to the frame by close fitting iron boxes. The frame is made of 3 by 4 inch oak scantling firmly mortised together. In front and back, a board is fitted into the frame at the underside of the frame pieces, thus making a long shallow trough, into which stones and other things may be put as picked up while the roller is at work. A cover for the roller, made of inch stuff in the manner shown in figure 2, is an important item if there is no shed under which the roller can be kept when not in use. This cover fits over the body of the roller and rests upon the

Fig. 3.—SEAT FOR ROLLER.

frame, and is so adjusted that it can remain in position when the roller is in use, but it is best to remove it unless the extra weight which it gives is needed to break the clods. Figure 3 shows the form of seat that may be put upon the roller for the convenience and safety of the driver. It consists of a board of sufficient strength to hold a person, and provided with long legs well braced. This "stool" is then fastened astride the roller in the middle, the lower ends of the legs fitting closely into the front and rear of the roller frame. The front end of the board may be shaped so that the driver may sit astride. The whole cost of a roller thus equipped is not great, and it will last for many years, with proper storing when not in use.

### Another Mouse Trap.

Mice are not the friends of man, and until they change their manner of living, or leave the country, traps to catch them will always be needed. The trap that will capture the greatest number of mice in the shortest space of time, and with the least expense, will be the best. Mr. J. B. Ritze, Franklin Co., Ohio, sends a sample of a trap of his make, which he has used with great success since 1847. It consists of a piece of board, on which two wood standards are placed, and these are united at the top by a short strip of wood. Through this top piece a round stick passes, carrying a heavy hardwood board of the same size as the floor of the trap, and held from whirling about by the standard pins, which pass through holes near the ends. The trap is set by raising the heavy board, and securing it in place by a key, and string, which runs down to the "tumble piece" of a "figure four," on the

A MOUSE TRAP.

outside of the trap. The trap is shown set in the engraving. As the mouse nibbles the cheese fastened on the end of the long stick of the "figure four," the "tumble piece" is thrown out, the key flies up into a slot in the stick, carrying the heavy board, and down comes the latter upon the mouse.

This trap can be made of almost any size, to suit the animal to be caught, and may be useful in taking larger "game" than mice. It is not patented.

### The Cabbage Worm.

The most troublesome pest to the Cabbage-grower is the green caterpillar generally known as the "Cabbage Worm." In some localities it has destroyed the entire crop, involving a loss of many thousands of dollars. After one of these visitations a locality will be comparatively free from them for some years, but they are quite sure to be troublesome somewhere every year. As with most other destructive insects, their great increase is accom-

panied by a still greater increase in their natural enemies, without the aid of which the cultivator would be much less successful in his warfare upon insect pests than he now is. The most destructive natural enemies of insects are other insects; these are often very minute, and some may attack the pest in every stage—egg, caterpillar, pupa,

Fig. 1.—COMMON COMB.

or in the perfect state. Many of them live within, and eventually destroy the host. The Cabbage Worm has several of these parasites, but the cultivator can not wait for them to do the whole work, he must resort to more rapid means when the enemy comes in force. For the aid of those to whom the insect is a new comer, we may say that the worm comes from eggs that are deposited on the under side of the cabbage leaves by a medium sized and rather pretty butterfly, which is white with a few black spots. These Cabbage-butterflies come early in the season, and are sometimes so abundant as to appear like a white cloud over the cabbage field. When such is the case it is evident that something must be done to destroy them or their greedy young, soon following them, will ruin the crop. Every female butterfly killed means the prevention of a multitude of worms and, therefore, a strike at the butterflies is the one that is most destructive. The butterflies may be caught by the use of an ordinary insect net, made by attaching a bag of mosquito

netting to a hoop fastened to a round stick, such as an old broom handle. Even when the butterflies are not so numerous as to seem threatening, catching should be persevered in. If the butterflies are neglected and allowed to deposit their eggs, the next best thing is to make war upon the cater-

Fig. 2.—ENGLISH COMB.

pillars; and the earlier this is done the better. The remedies effectively used in the case of the Potato Beetle, namely: Paris Green and London Purple, cannot be employed here, as it would be applying a deadly poison to the edible portion of the plant. The most successful remedy is hot water at about 160°—hot enough to kill the worms and not sufficiently hot to injure the plant. Apply the remedy at once, as the worms soon eat into the forming head.

### Curry Combs.

It is not our purpose to treat the subject of curry combs from an historical standpoint, interesting as it might be, but to simply call attention to a few of the forms or styles of combs now in use. A curry comb as it is now made consists, speaking in a general way, of thin bars of metal, arranged in parallel rows, presenting smooth or toothed edges, and provided with a handle of some sort, by means of which it can be grasped by the hand. In figure

Fig. 3.—HOTCHKISS' "SUPERIOR" COMB.

1, one of the simplest of the modern combs is shown, with six bars all provided with fine-toothed edges. The back is open, and the handle of wood extends from one side, and is joined to the comb by a trowel shank. Combs made in this form are of iron japanned, iron tinned, and of brass. An English pattern of a solid back comb is shown in figure 2, which is styled "extra heavy." There are eight bars upon the face; and two stout "wings," one on each side, are provided for striking the comb against any object, as the side of the stall, for the purpose of cleaning it. This form of comb is largely used throughout the world. In figure 3, Hotchkiss' "Superior" six bar, closed back, is shown. This differs materially from the English in the manner of the attachment of the handle, which has, besides the trowel shank, two rods passing to the front of the comb. Figure 4 shows the way in which this style of handle may be grasped by the hand when long strokes are to be made upon the sides or back of the animal. The "Champion" is shown in figure 5—a six bar, solid

Fig. 4.—METHOD OF HOLDING COMB.

back comb, with the trowel shank flat. A bent iron rod passes from one side of the comb to the other, making at the same time a part of the handle and the "dusting wings"—or "jar knobs," as they are variously called. The position of the hand in hard scrubbing with this form of comb is shown in figure 6. Of the "Novelty," which differs from the others in not having any wooden handle, there are several kinds. The one shown in figure 7 is the heavy eight bar, with open back. A close backed, one of the same style, is shown in figure 8, as also the manner of holding the comb. The loop made at one side receives the thumb, while the fingers grasp the bar that passes across the top of the comb. An easy side motion is gained with this comb with the hand in the position given. Figure 9 shows "Lawrence Perfect Comb," with the mane comb attached. The method of attaching the handle is by heavy wires, two of which pass along the back and sides, while two others pass over, and are fastened to the top in front. A great variety of combs of this style of handle are made, differing in the number of bars, and whether the backs are open or closed, etc. The manner of holding this form of comb is shown in figure 10.

Not a tithe of the curry combs that are in use are

here given—in fact, only here and there one from a long list of them. They are all so perfect that one can not go amiss in buying any of those illustrated.

As regards their use, it goes without saying that they are implements which no lover of neat looking, well cared for, and healthy horses will be without. Like all good things, curry combs have their place and their use; they can be abused; but the tendency is not in that direction.

**Milking and Milking Time.**—Any one who has had to do with dairy farming, knows that there are a great many poor milkers, against a few who understand and practice the proper method of removing the milk from a cow. It is a well-known fact that some persons can obtain more milk from a cow, with greater ease and in quicker time than others. In the first place, there must be an air and spirit of gentleness about the milker, which the cow is quick to comprehend and appreciate. It is not to be expected that a cow, and especially a nervous one, will have that easy, quiet condition so necessary to insure an unrestrained flow of milk, when she is approached in a rough way, and has a person at her teats that she justly dislikes. There must be a kindness of treatment which begets a confidence before the cow will do her best at the pail. She should know that the milker comes not as a thief to rob her, but simply to relieve her of her burden,

Fig. 5.—THE "CHAMPION" COMB.

and do it in the quickest, quietest, and kindest way possible. The next point in proper milking is cleanliness: and it is of the greatest importance if first-class milk and butter are the ends to be gained in keeping cows. No substance is so easily tainted and spoiled as milk; it is particularly sensitive to bad odors or dirt of any kind, and unless the proper neatness is observed in the milking, the products of the dairy will be faulty and second class. Those persons who can and will practice cleanliness while at the cow, are the only ones who should do the milking. It matters not how much care is taken to be neat in all the operations of the dairy, if the milk is made filthy at the start; no strainer will take out the bad flavor. Three all-essential points are to be strictly observed in milking: kindness, quickness, and neatness. Aside from these three is the matter of the time of milking. It should be done at the same hour each and every day, Sundays not excepted. It is both cruel and unprofitable to keep

Fig. 6.—POSITION OF HAND.

the cows with their udders distended and aching an hour over their time. We will add another *ness* to the essentials already given, namely: promptness.

### An Experiment in Deep Drainage.

Four years ago we laid a side-hill drain through a small pond hole at the depth of 15 inches, which

Fig. 7.—THE "NOVELTY" COMB.

was all that the fall allowed of at that time. The drain worked well, and carried off all the surface water that gathered, but failed to give maximum crops. Every season the area of shallow drainage has been marked by a stunted growth of cabbages, potatoes, beets, and carrots. The adjoining area which admitted of three feet drains, has given as good crops as could be desired. This spring we have dug a greater distance for an outlet, breaking through the rim of the basin that held the pond, and have put down tiles three feet, which works like a charm. The ground is cracking for several feet on each side of the drain, the water has disappeared, and the air has gone down after it. This ameliorating process going on above tile-drains is one of the most beautiful sights a cultivator can behold. Drains two and a half to three feet below the surface are a good investment in all wet or hard-pan soils. We notice, with great satisfaction, the rapid spread of tile-draining in some of the older Western States. Recent meetings of the tile manufacturers there show that in Ohio, Indiana, Michigan, Illinois, Wisconsin, and Iowa, they have 1,140 tile factories now, instead of 400 in 1870. During the last year they turned out 175,000,000 tiles, worth \$2,812,500. The average depth of laying the tiles is 33 inches, and the cost of digging is from 15 to 30 cts. a yard, but in the yield of crops the increase is from 25 to 100 per cent. The cost of tiles is \$6.25 per thousand, which is much below the prices we have to pay in the East. A stronger argument for thorough drainage by tiles than these brief statistics could not be presented. Even in the new States, where the soil is far from being exhausted, it is good economy to put down tiles. The good seed sown in the *American Agriculturist* from the record of Tim Bunker's Experiments in the Horse Pond Lot over twenty years ago, to the present, is springing up and bearing fruit. CONNECTICUT.

**Keeping Off the Bugs.**—We have frequently advised the making of frames to be covered with a pane of glass, for use in forwarding cucumbers, melons, and other semi-tropical plants in the garden. We have found these frames to serve a double pur-

Fig. 8.—USING THE "NOVELTY."

pose, in keeping the striped bugs from the plants as well as in keeping them warm. A correspondent, "C. W.," uses similar frames for the insects alone. He writes: "The best investment I ever made was a few cents for mosquito netting last season. I had tried almost everything before recommended as infallible protection against the

Striped-bug on vines by practical gardeners—dead clams, quassia water, soot, ashes, plaster, lime. Miserable comforters were these all. Heavy rains would wash off the upper sides of the leaves, and the under sides would always be exposed to the ravages of the bugs, so that eternal vigilance and much use of thumb and finger was the price of every squash, melon, and cucumber grown upon the place. But a few cents' worth of netting drawn over my bottomless box, or frame, large enough to cover the hill, makes light work of growing melons and cucumbers. Plant the seed as usual, and when the plants begin to make their appearance, the frames covered with netting are put over the hills. They need only be removed for the purpose of cultivation, until about the first of July, when the bugs disappear. Any store box, such as soap, starch, canned fruits, etc., are packed in, will answer.

### The Temper of the Horse.

In a prize essay upon the English Cart Horse, published in the "Agricultural Gazette" (London), the author treats his subject under ten heads, as follows: "1, the size—2, the carcass—3, the back and loins—4, the shoulders and fore legs—5, the feet—6, the hind quarters—7, the head and neck—8, the color and skin—9, the action—10, the temper." We quote the remarks under the last head, because they apply as well to our farm and other horses as to cart horses in England. "A really vicious stallion or mare should scarcely be devoted to the stud. We ought not needlessly to risk the lives of our-

Fig. 9.—THE "LAWRENCE" COMB.

selves or the attendants, and we should not therefore run the risk of breeding biters and kickers, for, without undervaluing the late Mr. Rarey's system, which we believe to be good, we yet prefer adhering to the principle that 'prevention is better than cure.' Of scarcely less importance as regards utility, although not dangerous, is another fault which has been stigmatized as a vice, and which, in purchasing a cart horse, we guard against by the proviso that the animal must be warranted a good worker. We allude to a hot or fretful worker. We may endure such fault in a hack or single-harness horse, but in a hunter or a cart-horse it is a sin which cannot be forgiven. Such an animal is an eye-sore to the master, and an annoyance to the attendant. When at work he is always fretting and sweating, and when at rest looks mean and miserable. Jibbers and restive horses are of course to be avoided; the former vice is more likely to be hereditary than the latter, which often springs from bad management or rough usage, but the want of stanchness to the collar, which is understood by the first appellation, is frequently innate—hereditary."

### A Rail Holder.

Robert Erdly, Snyder Co., Pa., who "finds in the *American Agriculturist* nearly all kinds of drawings

Fig. 10.—THE "LAWRENCE" IN USE.

and descriptions of machinery that are needful upon the farm," wishing to contribute his share, sends a sketch of a Rail Holder, which he has used for eight years and finds very useful.

Directions for the construction of the machine: "The piece A, is made of 2-inch plank, 6 inches wide and 4 feet long with a pin hole at each end, as shown in the engraving; B, is of the same material, 8 or 9 inches wide, 4½ feet long; C, is a 3 by 4-inch scantling about 5½ feet long, and D, is of the same material about 3 feet in length. The piece E, is of 1-inch board, 3 inches wide, 3½ feet long, with a cross-piece on top. F, is 3 by 3 inches, about 16 inches long; G, is 1½ by 2 inches, 4 feet long. The iron rod H, is ¾ of an inch thick; a chain will answer the same, if being about 21 inches long; I, of 1-inch board and 3 inches wide, about 3½ feet long with small holes. J, is an iron pin; K, an 1-inch board about 16 inches long, 3 or 4 wide; L, is 1 by 3 and 7 long; M, a curved brace about 16 inches long fastens with hinges to B; N, N, chopping blocks; O, the fence rail; C, and D, are made with sharp iron teeth in them, 1½ inch long, to hold the rail in its proper place, as shown in the engraving. In using this machine four stakes must be driven into the ground, one through the holes at each end of A, and one on each side of B, near the end at M, to keep the machine at its place. When a rail is ready to take out, draw out the pin,

A MACHINE FOR HOLDING RAILS.

J, raise up the lever, take hold of the beam C, and raise it up and place M under it; shown by dotted lines in the engraving; the rail is then loose, and the machine is ready, with its mouth open, for the next rail. This machine is also very useful for

hewing posts. Either one of the Blocks, *N*, can be laid against the machine to suit a right or a left-handed operator. The butt end of post must always be put in the machine. Every farmer or fence maker ought to have such a machine, as the rails can be pointed more regularly and with ease."

[FIRST PRIZE ESSAY.]

## The Family Cow, and How to Keep Her.

She's broad in her hips and long in her rump,  
A straight and flat back without even a hump.  
She's wide in her lips and calm in her eyes,  
She's fine in her shoulders and thin in her thighs,  
She's sleight in her neck and small in her tail,  
She's wide in her breast and good at the pail;  
She's fine in her bone and silky of skin,  
She's a grazer without and a butcher within.

—MILBURN.

There are several ways of providing for the wants of a cow, but in all cases it is absolutely necessary, in order to obtain the best results, that certain rules be followed with regard to the treatment the cow receives. She must be fed and milked at regular times, be kept thoroughly clean, have plenty of fresh air and water, and her food composed of those substances that will keep her always in good condition, do away with the milk bill, reduce the grocer's account, and contribute greatly to the health and comfort of the family. I have tried various things, and have found fresh grass or fodder, provender, bran, oil-cake, mangels, and hay, the best bill of fare for "Daisy" or "Buttercup." Avoid brewer's slops or grains as you would poison, for although they increase the flow of milk, it is thin and blue, the butter white and tasteless, and after a time the cow's teeth will blacken and decay. I was told the other day by a very intelligent dairyman that after feeding his cows one season on brewer's grains he was obliged to sell his whole herd.

Mr. Geo. E. Waring, Jr., in his "Ogden Farm Papers," says he expects to be able to feed a cow from May 15th to November 15th from  $\frac{1}{4}$  acre of ground, but the average citizen had better not attempt it, but keep his half acre to raise vegetables

PLAN OF COW STABLE.

and fruit, buying what food he requires to keep his cow. A cow can be made very profitable if kept in the following way: First, as to the accommodation required, a yard 15 feet by 15, and a stable or cowshed arranged as in the following plan. *A*, manure shed; *B*, bin for dried earth; *C*, cow; *D*, store-room; *E*, window for putting in hay; *F*, door; *G*, trap to loft; *H*, feeding trough. Her food to be provided as follows: Into a common wooden pail put one quart of provender (provender is oats and peas ground together, and can be purchased at any feed store),  $\frac{1}{2}$  lb. of oil-cake, then fill the pail nearly full of bran and pour boiling water over the whole; stir well with a stick, and put it away covered with an old bit of carpet until feeding time; give her that mess twice a day. Her dinner from June to November to consist of grass or fodder cut and brought in twice a week by some farmer or market gardener in exchange for her manure and sour milk. In Montreal, grass and fodder is brought to market by the "Habatants," and sold in bundles. As to quantity, a good big armful will be sufficient, and it is more healthful for the cow if it is a little wilted. In the winter, hay and mangels are to be fed in place of the grass and fodder. She should also have salt where she can take a lick when so minded, and fresh water three times a day. The yard should be kept clean by scraping up the manure every morning into the little shed at the end of the stable. The following table shows the food required to keep one cow well the entire year:

Hay, the best, 2 tons, at \$10 per ton.....	\$20 00
200 lbs. of oil-cake, at \$4 per 100 lbs.....	8 00
500 lbs. of provender, at \$1 per 100 lbs.....	5 00
$\frac{3}{4}$ ton of bran, at \$12 per ton.....	9 00
1 ton of mangels.....	5 00
	\$47 00

Your cow will require the following "trousseau":

1 five-gallon stone churn.....	\$1 25
1 $\frac{1}{2}$ doz. tin milk-pans, at \$2.....	3 00
1 milk pail and strainer.....	60
1 butter bowl (wooden).....	50
1 paddle and print.....	20
2 wooden pails for feed.....	40
1 card.....	25
	\$6 20

Cost of a good cow.....40 00

Interest at 8 per cent.....\$3 69

Any ordinary family will take from a milkman at least one quart a day. We in Ottawa pay 8 cents per quart, making per year  $365 \times 8c.$ , \$29.20.

It is a very poor cow that will not average 5 lbs. of butter a week for 40 weeks, and that at 25 cents per lb., that is, 40 weeks  $\times 5$  lbs.,  $\times 25c.$ , equals \$50.00.

So the account stands thus:

Butter.....	\$50 00
Milk.....	29 20
	\$79 20
Cost of food for one year.....	\$47 00
Interest on cow and trousseau.....	3 69
Profit.....	\$28 51

I have found that two acres of land is the least possible area that will provide cow-food for the entire year, and that should be divided thus: One acre for hay, the other for fodder and mangels. If you have no land already seeded down, plow up your acre, sow clover and timothy, 6 lbs. of each. In May, when the grass has fairly started, top-dress it with two bushels of land plaster; if you can apply it just before a rain it is the best time. The first year you will have all clover hay, and it must be cut before the second blossom comes; if not cut early enough, the stalks become tough and woody, and are wasted by the cow. The second year, if top-dressed in the fall with the manure collected during the summer, you will have a fine crop of timothy, and if the land was good for anything you can cut hay from it for three years by giving it a little manure every fall. As early as the ground will admit, sow some peas and oats; one bushel of each will plant one-third of an acre. Peas do well on old sod, and are the best crop to plant on new ground. In about six weeks you can commence cutting it for fodder, and it should give the cow two good meals a day until corn comes in. L. B. Arnold, in "American Dairying," says of corn: "When too thickly planted its stems and leaves are soft and pale, its juices thin and poor. If sown thin or in drills, so that the air and light and heat of the sun can reach it, and not fed until nearly its full size, it is a valuable soiling plant." Now Mr. Waring, in "Farming for Profit," says: "It is a common mistake when the corn is planted in drills to put in so little seed that the stalks grow large and strong, when they are neglected by the cattle, the leaves only being consumed. There should be 40 grains at least to the foot of row, which will take from four to six bushels to the acre, but the result will fully justify the outlay, as the corn standing so close in the row will grow fine and thick." My experience tells me that Mr. Waring is right; any way, my cow will not eat the coarse stalks which will grow when the corn is planted too thin.

The one-third acre reserved for mangels, must be the perfection of richness, well drained, and manured. If the soil is deep, you can plant them on the flat, but if the soil is shallow, plant them on ridges, the ridges 30 inches apart, (I always plant them in that way); then thin out the plants to 15 inches apart. Ten to twelve hundred bushels may be grown on an acre, but the ground must be properly prepared. In storing them, they require to be very carefully handled, as the least bruise hastens decay, and we want to keep them fresh and good until April, when our cow ought to give us a calf.

I thought I had tried almost everything relating to the care of cows, but when I undertook to wean a five weeks' old calf, I found my education in that respect sadly neglected. I asked a farmer's wife how I was to manage, "Oh," she said, "just dip your fingers in the milk, and let the calf suck them a few times, and it will soon learn to put its nose in the pail, and drink." It sounded simple enough, so I took my pail and started for the barn, where that wretched animal slopped me all over with milk,

bunted me round and round the pen, until I was black and blue, sucked the skin off my finger, and wouldn't drink. After trying at intervals for two days, the calf was getting thin, and so was I. In despair, I left the pail of milk, giving that calf a few words of wholesome advice. When I went back two hours after, the calf was standing over the empty pail, with an expression on its face, that I translated into an inquiry, as to why I hadn't left that pail there before. I have weaned several calves since then, but have never had any trouble. Leave them with the cow 3 or 4 days, then take a little milk and hold the calf's nose in the pail, it must open its mouth or smother, and when once it tastes the milk, will soon learn to drink.\* When it is a week old, commence feeding with oil-cake, skim milk, and molasses. Into an old 2-lb. peach can, I put one tablespoonful of oil-cake and one of molasses, fill up the can with boiling water, and set it on the stove until thoroughly cooked. That quantity will be its allowance for one day, mixed with the skim milk. The next week give it that quantity at each meal, and the next week twice that. The calf will then be four weeks old, and the butcher ought to give you a price for it that will pay for all trouble and the family milk bill while the cow was dry. It does not pay to raise calves where you only keep one cow. (Mr. Cochrane, the owner of the celebrated cow, "Duchess of Airdrie," told me the other morning that last year he sold a calf of her's to an English gentleman for 4,000 guineas (\$20,000). I think it would pay to have a wet nurse if one had a calf like that). A tablespoonful of lime-water put in the milk now and then will prevent the calf from "scouring," a complaint very common among calves brought up by hand. I believe that winter rye makes a valuable soiling plant, but I have never tried it.

### A Few Words as to General Management.

I think it cruel to keep cows tied up all summer. They do not require much exercise, but fresh air they must have, and it is a great comfort to them to lick themselves, although they ought to be well curried every day. It is better to milk after feeding, as they stand more quietly. Don't allow your milk-maid to wash the cow's teats in the milk pail, a filthy habit much in vogue. Insist on her taking a wet cloth and wiping the cow's bag thoroughly before she commences to milk. A cow ought to be milked in ten minutes, although the first time I undertook to milk alone, I tugged away for an hour. I knew how much milk I ought to have, and I was bound to get it. An old cow will eat more than a young one, but will give richer milk. If you can get a cow with her second calf, you can keep her profitably for 5 years, when she should be sold to the butcher. There is nothing that will keep your cowshed so neat, and add so much to the value of your manure pile, as a few shovelfuls of dry earth or muck thrown under the cow. It will absorb the liquid manure better than anything else. Don't allow your milk pans to be appropriated for all sorts of household uses; you cannot make sweet, firm butter if the milk is put into rusty old tin. Skim the milk twice a day into the stone churn; add a little salt, and stir it well every time you put in fresh cream. Use spring water, but don't allow ice to come in contact with the butter; it destroys both color and flavor. If your cream is too warm the butter will come more quickly, but it will be white and soft. When the cream is so cold that it takes me half an hour to churn, I always have the best butter. Don't put your hands to it, work out the buttermilk with a wooden paddle, and work in the salt with the same thing. There is an old saying that one quart of milk a day gives one lb. of butter a week, and I think it is a pretty fair rule, but don't expect to buy a cow that will give you 30 quarts of milk a day. There are such cows I know, but they are not for sale. Be quite satisfied if your cow gives half that quantity. Place the cow's food where she cannot step on it, but

\* It is better, as a rule, not to allow the calf to suck at all. The aptness to learn to drink is influenced largely by heredity. Calves from ancestors that have not been allowed to suck, learn to drink more readily than those which have been allowed to run with the dam.—ED.]

don't put it high up; it is natural for them to eat with their heads down. I think it is better that the family cow should have a calf every year, provided you can have them come early in the spring or late in the autumn. As to the time that a cow should be dry, that depends much upon the way the cow was brought up. If she was allowed to go dry early in the season with her first calf, she will always do it. A cow being a very conservative animal, she should be milked as long as her milk is good. When she is dry stop feeding the provender, bran, and oil cake, give her plenty of good hay, with some roots, until after she calves. The provender and oil cake being strong food, are apt to produce inflammation and other troubles at calving time. You can feed turnips when she is dry, at the rate of two pails a day, cut up fine of course, but don't feed turnips when she is milking. I have tried every way to destroy the flavor of turnips in milk, but without success. I have boiled it, put soda in it, fed the cow after milking, but it was all the same—turnip flavor unmistakable—and as we don't like our butter so flavored, I only feed turnips when the cow is dry.

The Rev. E. P. Roe in his delightful book called "Play and Profit in My Garden," says: "If a family, in ordinary good circumstances, kept a separate account of the fruit and vegetables bought and used during the year, they would, doubtless, be surprised at the sum total. But if they could see the amount they could and would consume if they didn't have to buy, surprise would be a very mild way of putting it." The same rule applies to the keeping of a cow. We buy one quart of milk a day and manage to get along with it. Our cow gives us from 10 to 20 quarts a day, and we make way with the greater part of it. I think with a cow and a garden one may manage to live, but life without either, according to my ways of thinking, would be shorn of many of its pleasures. "BUTTERCUP."

(MRS. G. BOURNOT, House of Commons P. O.,  
Ottawa, Canada.)

### The U. S. Signal Service and Farmers.

The benefits of the United States Signal Service in the weather indications furnished at the various ports have been of untold value to commerce; indeed, it can never be known how great has been the saving of life and property due to an observance of the "Danger Signals," set at its stations. In a measure the usefulness of the Service is to be extended to Agriculture, and arrangements are being made so that farmers living beyond the reach of the daily weather reports may of themselves, by a little careful observation, make forecasts of the weather much more accurately than they could without the aid furnished by the Signal Service.

The Weather Case, an engraving of which we are enabled to give through the courtesy of Gen'l Myer, the efficient chief of the Service (and known to so many by the familiar, but not disrespectful title of "Old Prob."), is made upon the principle that no single instrument is of much value as a weather indicator. Barometers have greatly fallen in public esteem because the makers foolishly mark on them "fair," "rain," etc., it not being possible for the instrument to give any such positive indications. A reading of the barometer with the wind in one direction, may indicate very differently from what it would with the wind in an opposite point. It is only when the tendency of the barometer is taken with the direction of the wind, and to these observations are added those of the Dry and Wet-bulb thermometers, and the character of the sky at sunset, that a tolerably accurate forecast can be made of the weather for the next day. Our object is merely to describe the instrument—or rather set of instruments, the whole being called "The Weather Case, or Farmers' Weather Indicator." As each case is accompanied with full and minute descriptions, with directions for making observations and deciding from these what are the "indications," we need only describe the different parts in general terms. At the upper part of the case is the Barometer, the circle with a graduated one within it and a long and short pointer. The Barometer with which our

readers are most familiar is the Mercurial, a long tube containing mercury. In the Case a form of barometer called the *Aneroid* (a made up word meaning *not wet*, as it contains no liquid) is used—only the dial is shown—it is a circular box of thin metal and partly exhausted of air. As the details would not be understood without an engraving, suffice it to say that this box is so arranged that its thin sides will change position with the pressure of the atmosphere; they will be pressed

towards one another when the air is heavy, and move apart when it is lighter. This motion is communicated to the short hand seen upon the dial, upon which are degrees corresponding to the inches of a mercurial barometer. It is the short hand or pointer which is moved by the barometer; the long pointer is moved by hand to be directly over it, and to allow any changes made by the shorter one to be noticed. It also points to a graduated arc above, which we need not describe any further than to say that all above the circular dial is a contrivance for showing the mean barometer reading of the place for the month, and that its use is fully described in the circular.

At the right and left of the barometer scale are disks for recording the length of time the wind has been in a particular direction. Next below on the left is the Wind Disk, to be set three times a day to show the direction of the wind. Opposite this is the Sunset Disk. A semi-circular opening has behind it a disk, half of which is red and the other half blue. If the sunset was a fair weather one, the disk is to be turned to show its red half; if foul, its blue half, or if doubtful, then parts of both colors are shown. Below are the Thermometers. That at the left is an ordinary thermometer; the one at the right is just like it, except that its bulb is covered with cotton wicking, which is kept wet by having its lower end in a fountain arranged to hold a supply of water. The Wet-bulb thermometer shows whether the atmosphere is moist or dry, and is a most important aid in weather observations. Every one knows that clothes will dry more rapidly in a dry air than in a moist one; if the finger be wetted, and held in a dry current of air, a sensation of coolness will be felt. The Wet-bulb thermometer acts upon these two principles, that evaporation produces cold, and that evaporation is more rapid in a dry air than in a moist one. As water evaporates from the bulb of one thermometer, that will be cooled, and its reading be lower than that of the other thermometer just like it. Between the two thermometers are arrangements for showing how far apart the two thermometers are at any given time. In dry weather they will be farthest apart; if the two readings are coming nearer together, the air is growing more moist—one of the indications of a change. By a careful study, according to the directions given, of the changes that occur from day to day, an ob-

servant person may soon learn to foretell the weather with a useful degree of accuracy and certainty. The real Case is 31 inches high, 13½ inches wide, and about 4½ inches thick. The front is covered by a glass door, which is kept closed except when making observations and adjusting the different instruments; it resembles a clock.

The whole thing being quite new, we are not able at this time to state how and where the cases are

THE WEATHER CASE, OR FARMER'S WEATHER INDICATOR.

to be distributed. In a general way we understand they are to go to those agricultural centers at a distance from large towns where the regular weather report is received daily, or twice a day, and where they will be of use in foretelling the weather for that locality. It is probable that we may be able to give something more definite next month.

### A Hogshead Sheep Rack.

Mr. D. E. Manter, Kennebec Co., Maine, finds that a very convenient rack for a few sheep can be made in the following manner: An ordinary molasses hogshead is taken, and one of its heads re-

moved. The alternate staves in twos are cut away, in the manner shown in the engraving, thus making feeding places for a half dozen or more sheep. A rack of this kind can be made at very little cost; is handy to put the fodder into, and

A HOGSHEAD FODDER-RACK.

certainly can not be objected to by the sheep, as each one has a full and equal chance to feed from it.

### Water Supply for Barns.

Mr. S. J. Boyd, Orange Co., N. Y., sends sketch, and writes: "In April 1876, I moved upon a farm where water was scarce around the barn. During the summer I dug a well on a dry side-hill above the barn, and some 20 rods distant. The well (7 ft. in diameter, by 27 ft. deep), was so far above the barn, that it could be dug somewhat deeper, and then draw water from the bottom of the well, to the barn, with a siphon. Eighteen ft. of the 27 dug, was through very hard slate rock, which was loosened with Common Rock, and Giant Powder, the latter doing greater execution with the same drilling, and much more convenient, as water does not injure it in the least while blasting; in fact, I used water alone for tamping. After reaching the depth of 27 ft., I stoned up only from the top of the rock, about 9 ft. The well then having cost considerable, and not being entirely satisfied with the supply of water, I did not care to spend any more money laying pipe, etc., until there was reason to believe the supply of water was sufficient to keep at least a small stream of water constantly running. November 18th, 1878, I finished laying a half-inch lead-pipe from the well to the barn, and started the water running. Although last winter was a cold one, and many farmers were short of water for their stock on account of the long cold spell of weather, my rock-well gave a stream of water and did not fail, neither has it failed up to the present time, (Dec.

PLAN OF HILL-SIDE WATER-WORKS.

2nd, 1879.) This gives me every reason to believe that my dry side-hill water-works are a success, and the convenience for cooling milk, and watering stock, is worth more than the interest on the cost of the well, lead-pipe, etc., which at present prices, would amount to about \$100."—[The accompanying engraving shows the method which Mr. B. has found so satisfactory, and it may suggest to others having a side-hill farm of a similar nature, that a like investment may greatly benefit them.—Ed].

### Prickly Comfrey.

The *American Agriculturist* was one of the first journals to bring Prickly Comfrey into notice, and while we were very guarded in what was said about it, there are so many who take the mere mention of a new thing as an advertisement, we were quite desirous that it should not turn out to be a failure. Singularly enough, since we published an account of its being planted largely in Massachusetts in the spring of last year, not a single report came to us. This spring several inquired as to the present status of the plant, and wishing to know ourselves the present opinion of those who have grown it longest, we made the inquiry of Mr. Ashburner, of Virginia, the gentlemen whose communication we published with our first article on the subject. Mr. A. writes, that he has no new facts either for, or against the plant, and is "still of the opinion that it is a very valuable fodder plant, and worthy of a place on every farm in America." Mr. A. was the first in the country to import the Comfrey, and at first sold the plants, but he writes that he gave up the sale, among other reasons, because he did not care to be subject "to gross insult, from buyers who could not, or would not take the trouble to cultivate it properly, and then would not take the trouble to educate their stock to eat the fodder, when grown." This no doubt touches the cause of whatever lack of success it may have met with, for animals do not take to it at first, any more than wild horses will to corn, or people who never have eaten them, to olives. It takes a few days feeding, mixed with other food at first, before the majority of animals will accept and eat it by itself, and few will take the trouble. Mr. A. says, and we think with truth: "Unless farmers will cultivate carefully their Comfrey, and give it a plenty of manure, they had better not trouble it;" he adds: "I look upon Prickly Comfrey as the most valuable green food for pigs, as far as my experience goes, and fresh pork fattened on it is worth eating." On the whole, we think that the plant is one that will be useful to those who will take the trouble to make it so; in hit-or-miss farming it has no place.

### Flax and Flax Machinery.

No country can be regarded as really independent of other countries unless it produces not only all the food, but all the clothing material it consumes. So far as cotton and wool are concerned, we produce an abundance, but for flax and the fabrics made from it we are largely dependent upon others. Three agricultural products seem to make very slow progress in this country: sugar, from beets, oils, such as rape, colza, etc., and flax and similar fibres. One reason why these have not become important products of our agriculture is, because the farmer can not convert the raw material into a salable product, as this either requires expensive machinery and skilled labor to use it, or the processes by hand are

slow, and, of course, costly. If the farmer is to be expected to produce the raw material only, he must be assured of a market before he will undertake its culture. Capitalists are not ready to establish factories until sure of a supply of raw material, and it takes a long time to establish the proper relations between the two—the farmer and the manufacturer. In the case of sugar, good progress has been made within a few years, and it looks as though we might, within a short time, cease

to import sugar. In the matter of oils, our wonderful stores of petroleum, and the improvements in utilizing the heretofore almost wasted cotton-seeds, make it little necessary for us to seek any other sources of oils for burning, soap-making, etc. With flax and other fibres, one great obstacle to their profitable culture has been the slow processes of bringing them into marketable condition, which, at our prices for labor, made the raw material too costly. Every invention that tends to diminish this labor is of the greatest importance to the agriculture of the country. It was with no little interest that we recently watched the working of the

FLAX MACHINE.

machine of the American Vegetable Fibre Co., of Philadelphia, which breaks and scutches the flax at one operation in the most rapid and complete manner. The engraving shows the general appearance of the machine, which is very compact, taking up no more room than an ordinary grain fanning mill. The bunch of flax being spread upon the table in front of the machine, the stalks are caught in a set of grooved rollers, these by their peculiar motion cause the breaking, when the flax passes on to the scutchers, placed in the elevated part of the machine; after being subjected to their action for a short time, it depending upon its condition, the flax comes back, is turned, and the other end is submitted to the same operation. All of this takes but a very little time, and at the last motion the workman has the flax in hand, beautifully clean and shining, with not a fibre tangled or displaced. The operation is as thorough as it is rapid, a careful examination failing to discover any appreciable amount of boon remaining to be removed by the hackle. The officers of the Fibre Company are very enthusiastic over their machine and its effect upon the agriculture of the country, and when they assert that the machine "bids fair to give a new history to the whole business"—referring to flax-growing—we can not think them extravagant. One of these machines in each flax-growing township would make a vast difference to the profits of the farmers. To those who now raise flax for the seed, the machine will be of the greatest value, as by proper care in handling they may get a crop of fibre as well as one of seed. If seed is to be saved, the flax is harvested when the stem has lost its green color for two-thirds of its length; it is made into small bundles, and the few inches of the seed-bearing portion of the tops cut off with a hay or straw cutter having a single lever-knife; the stalks are then ready for rotting in the usual manner. We did not see the machine work upon hemp, but samples of the fibre that had been broken by it showed that it is equally useful for that crop. We so thoroughly believe in a diversified agriculture that we gladly welcome any improvement that will allow our farmers to add another to the crops which they may grow with profit, and think it will be well for those who have land suited to flax, to consider whether they might not find it to their interest to undertake its culture. We have recently learned that a machine has been invented in New Jersey which does for Ramie and similar plants what this machine does for flax; thus the subject of fibre production is rapidly increasing, and we shall watch its development with the greatest interest.

### California Fritillarias.

Those who know the stately Crown Imperial, with its corona of inverted flowers as large as tulips, lifted 3 feet or more upon a sturdy, leafy stalk, would hardly recognize in the delicate flower here figured any close relationship, much less suspect it of being an own brother. We are aware that some botanists do not regard Crown Imperial as belonging to *Fritillaria*, but whatever they may do with it, the relationship will remain as close as ever. California is rich in plants of the Lily Family, there being a large number of charming species, though they are as yet rarely seen in cultivation. Of *Fritillarias*, the excellent recent monograph of the Family, by Mr. Watson, shows California to have nine species, of which the one here shown, if not the largest, is by far the most showy. The bulb, about an inch in diameter, has many short and thick scales, and is in appearance unlike the exotic species. In this plant the stem is from 12 to 18 inches high, and bears whorls of narrow, pointed leaves, like those in the engraving, and at the top one to three, usually, but sometimes as many as seven, flowers, about an inch long, of an elongated bell-shape. It will be noticed that the tips of the petals are strongly bent backwards, which is not the case with the other species, and on this account it was called *Fritillaria recurva*. The color of the flowers is usually a bright orange scarlet, but sometimes crimson, which makes them decidedly showy. The plant was originally discovered near Sacramento, and is found in various parts of the Sierra Nevada. A few years ago it was sent to us from Sierra Co., as the "California Tulip," a name also given to more than one other plant. Another species which we have (April 26) just coming into bloom, is *Fritillaria pudica*; this has bright lemon-yellow flowers, which are much larger and broader bell-shaped than this. Besides these with red and yellow flowers, *Fritillaria lanceolata*, with its blotched and marked blackish-purple petals, like the old "Guinea-Hen Flower" (*F. meleagris*), presents a marked contrast in colors. Nearly all the species are desirable, and will no doubt be popular when we learn to treat them properly. The bulbs we planted last fall flowered freely this spring; what will be the effect upon the bulbs of our wet autumns after a dry summer, remains to be seen. In California, rains coming after a long season of rest through dryness, announce the beginning of spring; with us, it is the beginning of winter. Should au-

colchortus, and related bulbous plants, the flowers of which, though not as a general thing very large and showy, are often of such quiet beauty, that we would not abandon their culture, if any amount

A CALIFORNIA FRITILLARIA (*Fritillaria recurva*).

of pains-taking, and observance of their peculiar wants will allow us to obtain success with them.

### Alpine or Rock-Work Plants.

Nothing about modern gardening is more apt to be misunderstood than rock-work. Most plants that will grow in flower pots can be made to grow

can all this be done, but it is done, and it is a rock-work indeed, for there is nothing in the thing, its place, or the plants with which it is filled, that is not thoroughly artificial, while the only reason for having a rock-work at all is, that it introduces a bit of natural scenery where it did not before exist, and allows us to bring variety into the grounds. Unless there is some nook or corner about the place where rocks might naturally occur—and if they did so occur on the lawn they should be blasted out—it is better to leave the rock-work to those who have a proper place for it. But our object is not just now so much the rock-work itself, as the plants proper to grow upon it. Begonias, Geraniums, and bedding plants generally are entirely out of place on the rock-work, as they, for the most part, do much better in beds or in pots, and their whole port and bearing is a protest against planting them there. It is on the high mountains that natural rock-work is seen in its greatest perfection, and there we find plants, usually of low stature, spreading themselves over the surface of the rocks and blooming freely, while their long and fine roots are far down in the cool soil that fills the crevices. But as rocks are not confined to the high elevations, so the plants suited to the rock-work need not of necessity be those naturally alpine. Indeed, in gardening works the term "alpine" is applied to many plants that never get above the general level. In the high regions

of terrific storms and on the edges of perpetual snow, the only plants that can live are those of a low stature; only such as are found here are properly alpine, but in a garden classification other plants of low stature and similar compact habit are included also. The term rock-plants or rock-work plants is coming into use in place of "alpine," and is preferable, as it is equally definite and much more accurate. We

THE BALEARIC SAND-WORT (*Arenaria Balearica*).

turn start the bulbs into growth, that will be the end of them. It will then be necessary to take up the bulbs when the leaves die off, and keep them out of the ground as late as possible before planting. Not only the *Fritillarias*, but the various species of

in pockets of earth in a pile of rocks. This pile of rocks can be placed in the middle of a lawn, and as the rocks are apt to be of different colors, they can be made to look all alike by a coat of cement, or still worse, of whitewash. Not only

THE ROCK LYCHNIS (*Lychnis Sagascea*).

not long ago, at an exhibition, heard a plant spoken of as "a lovely little alpine," that never knew a higher station than the pine-barrens of New Jersey, but it was a "lovely little" rock-plant. In saying that the rock-work should not rise as an irruption

(or eruption) upon the lawn, it is not on account of the exposure, but as in bad taste; the rock-work need not be in the shade; it may be placed there, but then the plants selected for it must be of shade-loving kinds. The true alpinics have the most complete exposure, at least all parts but the root, and that has the most complete protection. In artificial rock-work success largely depends upon imitating these conditions for the roots, hence in constructing the rock-work, closed pockets should not be made, but crevices of various sizes, and the earth in these should connect with the soil below, so that at a distance below the drying sun and air the mulching influence of the rock will be aided by capillary attraction in keeping the soil of the crevices genially cool and moist. One may devote a rock-work to special classes of plants, or to a variety; ferns, many of which are well suited to rock-culture, make a pleasing collection; the succulents, including the Stone-crops and House-leeks, the hardy Cacti, and others form an interesting collection of curious forms, but most persons will prefer a variety, and their tastes may be gratified by collecting suitable and inexpensive—but not less beautiful wild-flowers, or by the purchase of exotics suited to the purpose. Among our natives the Early Saxifrage, the charming Bluets (*Houstonia*), Trailing Arbutus, Wind-flower, Rue Anemone, Columbine, Harebell, Moss Pink may be mentioned; these show what beauty and variety may be found among our native flowers without naming a host of others equally pleasing. So popular have such plants become in England that Mr. Robinson's book on "Alpine Flowers for English Gardens," as stated some time ago, has passed to a second edition, and one who would know about the numerous list of these plants should consult that work. Most of our florists offer more or less of the exotic alpinics, and they are made a specialty by a few; whenever there is a demand for such plants it will be met by our enterprising dealers. In looking over a collection of such plants at the establishment of Messrs. Woolson & Co., we selected two of the newer kinds—new to this country—as showing a habit of growth very effective upon a properly constructed rock-work where there are miniature steeples or rocky shelves, over which some plants can trail their stems or hang down in diminutive garlands. The Rock Lychnis, *Lychnis Lagascea*, is from the Western Pyrenees; it is a free-grower, quickly forming a mat of stems and foliage, and producing in early summer a great profusion of rosy-pink flowers like those shown in the engraving. It is especially valuable in not requiring much moisture, but will flourish in the driest parts of the rock-work. The Balearic Sand-wort, *Arenaria Balearica*, from Corsica, is remarkable for its foliage, which is of the most diminutive kind; its leaves seem more like those of a Selaginella than of a flowering plant, and in the mass make dense mossy cushions or a tiny carpet of the most pleasing verdure. Unlike the other this prefers a fairly moist situation, where it will cling to the rocks and throw out roots against their bare face. The tiny flowers, each upon a slender stalk an inch or so high, appear against the dark green like little pure white stars. The engravings show both plants of the natural size, and they both may be cultivated in the garden border, or even in pots if it is desired to do so.

A Tree-Scraper.

A short-handled hoe is the implement generally used for scraping the trunks of neglected and moss-grown trees. Mr. W. E. Bower, Clark Co., Ind., sends a drawing of a Scraper which he prefers to any other. A piece of inch-board 8 inches long

and 3½ inches wide has a curve cut upon one side an inch deep in the center. A piece of strap-iron 1½ inch wide is nailed to both the curved and the straight edges of the board, which are bevelled to meet them. A handle 20 inches long is fitted to a hole in the center of the board. Mr. B. uses the curved edge first, with an up and down movement, which removes all the loose scales of bark; if any fragments escape, an application of the straight edge will displace them.

### The Elderberry Fungus.

Anything that is out of the ordinary run of things—is, in other words, a little strange—will in most cases find its way to our office with that question of all questions, "What is this?" This year we will anticipate a call for information by presenting a drawing, with a brief description, of the fungus which attacks the leaves and young branches of the common Elderberry (*Sambucus Canadensis*). This parasitic fungus belongs to the same group as the well known wheat rust; and as found on the Elderberry it is of the "cluster cup" form. It is

THE ELDERBERRY FUNGUS.

to be remembered in the treatment which the *Wheat Rust* received in August last, that it was shown that there were certain distinct states through which the rust plant passed, one of which was upon the Barberry, namely, the "cluster cup" form. The form upon the Elderberry is this "cluster-cup" one. Where the other states of the Elderberry fungus grows is not known.

So far as the Elderberry shrub is concerned, this parasite is not specially injurious to farmers, because the *Sambucus* does not take any high rank as a fruit-producing plant. As the matter now stands, the fungus in question is more curious than injurious. The way the fungus attacks the young branches and leaves is often very striking. We have found them, and had them brought to us, where the stem for a foot or so was swollen to several times its natural size, and twisted into all sorts of shapes; the surface for the whole length being covered with minute pits or cups, each filled with a vast multitude of orange-colored spores. The specimen from which the illustration is made is scarcely up to the average, but shows how thoroughly deformed the top of the branch has become; in fact, the growth of it has been entirely arrested by the fungus. One of the leaflets is seen to be rolled up, and its base greatly swollen, the surface of which is covered with the pits above mentioned; a few of them are shown in magnified view below and to the right. Small knots or enlargements are seen on some of the other leaflets, and one of some size at the union of the whole leaf with its stem.

The remedy, if it is desired to apply one, is the knife, removing all affected parts in early spring, which then should go at once into the fire.

### Horticulture at the Railroad Stations.—

A trip over the railroad between New York and Philadelphia, by the way of Bound Brook, the first since Centennial days, we were glad to notice the im-

provements at the stations. The grounds around the stations, some of half an acre or more, and others not larger than a city lot, had been put in beautiful order. Grass, evergreens, flowering shrubs, and in some cases flower-beds, made these usually desolate places charming spots for the eye to rest upon. They had an air of care and neatness that must exercise an influence throughout the neighborhood. But this road is not alone in well doing; happening to meet Mr. Hayes, a well-known horticulturist of Philadelphia, he informed us that he had the contract for laying out and planting the stations on the line between Philadelphia and Baltimore, some of which are of considerable extent, and occupy both sides of the road. The examples of these roads will soon find followers, for the improvement is so great as to commend itself to the most indifferent.

### Gardening in Public Institutions.

BY PETER HENDERSON.

A number of the Public Charitable Institutions in all parts of the country have farms, gardens, and even greenhouses are attached, the work required by these being mainly done by the inmates. In some these grounds are exceedingly well managed, and are a source of no little revenue, while others are actually worked at a loss, either from uncongenial soil, or from inefficiency in the management. One of the best managed gardens of this kind that has come under our notice, is that of the State Hospital for the Insane, Mendota, Wisconsin, at present under the superintendence of Dr. D. F. Broughton. Having heard reports of its satisfactory garden management, I recently wrote to Peter P. Schotzka, the intelligent gardener in charge, and obtained the facts here given: The present area under cultivation is about 22 acres, about one-half of which (10 acres) is planted with potatoes, the remainder is devoted to vegetables of almost every kind found in the markets, together with grapes, strawberries, raspberries, melons, etc., all of which are consumed in the Asylum. This Institution numbers nearly 700 persons—about 100 of whom are employees. To supply this large family 8 bushels of strawberries are used at a meal, 250 lbs. of grapes, 150 water-melons, or 300 musk-melons. The market value of the whole garden products in 1879—which was a year far below the average—was \$3,572. The expenses were: labor, \$1,400; manure, \$250; implements, \$75; seeds, \$75—making \$1,800 in all, leaving a net profit of \$1,772, or in other words, this sum was saved to the Institution by its growing, instead of buying its vegetables and fruits. But this was not the only advantage, the fruits and vegetables were fresh from the grounds, making them vastly more valuable than if packed and shipped from a distance. But the most important feature of the garden operations at this Asylum is the employment of the patients as workmen; an average of 15 are employed in the summer months, during the growing season, who work on an average six hours each day, and Mr. Schotzka, who is evidently a careful and intelligent observer, assures me that the effect on the health of the patients is most marked. They mainly volunteer, or are kindly coaxed to the work, and this labor in the open air, while it gives them occupation, directs their attention from themselves; the result is, that a greater number of the garden hands have been discharged as cured, in proportion to numbers, than of others.

No greenhouse is yet attached to the Asylum, but Mr. Schotzka manages, by the aid of hot-beds, to fill numerous beds that are laid out in the lawn in front of the hospital, with flowering plants. These he quaintly terms an "eye pasture" for the patients. These beds give flowers enough to form bouquets for the sick wards during the summer months, and thus are a source of great pleasure to scores of the unfortunates within. Believing in the soothing effects of flowers on some species of insanity, a gentleman recently left a fund of \$10,000 to be used in building a Winter Garden or Conservatory, to be used as a promenade ground for use of the patients at an Insane Asylum in Ohio.

The successful example of the Mendota Asylum is one well worthy of imitation, and such a garden might be attached with profit to various other kinds

of public institutions, for in nearly all cases the labor could be mainly done by the inmates, not only without cost, but to their physical, mental, and moral advantage. The grounds surrounding the various public buildings on Blackwells Island, New York, and at Flatbush, Long Island, are, and have been so for many years, models of excellent cultivation, and reflect credit on the management; but there are many others in the suburbs, and hundreds in all sections of the country, where no attempt whatever has been made, and in others it is so feeble that it has amounted to nothing. There is no excuse for this. There are always men fitted to take charge of such work, to be had for moderate salaries, who, with the free labor by the inmates of the institutions, many of whom would like the work, could produce crops that would add vastly to the comfort and health of the inmates, to say nothing of the saving to the county or State.

### Census of Forest Trees.

"A chiel's amang you takin' notes," or soon will be among the farmers about the forest-trees, and the care taken of them, and the uses made of them. Professor Sargent, the Special Agent for the Forestry of the Tenth Census, has had printed and widely distributed: *A Catalogue of the Forest Trees of North America*, of 93 pages, including a full index. It is printed on one side of the paper, so that there is a blank leaf facing every page of print. This is for making notes on. The trees are arranged under their natural orders; the botanical name is followed by the English names, then the geographical range is given, then the character of the wood, the size and port of the tree, and the known uses it is put to. If any one knows any of the trees outside of the range assigned to it, or knows any other uses of its timber, its bark, its fruit, etc., or knows any tree particularly remarkable in size or age, or otherwise, he is to make a note of it on the blank page, and send it by mail to Prof. C. S. Sargent, Brookline, Mass. If the sender wants to have his catalogue back again, to keep—as we suppose he generally will—the Professor will return it, or a fresh copy. Every one who can will wish to contribute to the Census Report on American Trees and Forests.

**American Yellow-wood.**—The Ladies' Garden Club of our Street, taking several horticultural periodicals, some of them English, occasionally get bits of news which are not quite adapted to our meridian, and which therefore puzzle them. For instance, Mr. Burroughs, in "The Garden" (London), for March 6, gives a glowing account of the above named tree, "or rather shrub," as he says, which "commonly attains the height of 15 to 18 feet," though indeed he does know one more than 30 feet high; and he says "it has handsome yellow flowers." The ladies ask me what all this can mean. For all the old trees here are at least fifty feet high, and the younger ones grow apace, as if not meaning to be left behind. Then they know that the flowers are white, and are a deal handsomer than Mr. Burroughs allows. The meaning of it all is that this noble tree does not get summer enough in England, and hardly ever blossoms there. The author of the article, who says he has seen few specimens there, should have said that he never saw it in blossom; and he probably jumped to the conclusion that the flowers are yellow, because the botanical name is *Virgilia lutea* (or *Cladrastis lutea*), though he might have guessed that the "lutea" or yellow referred to the wood. He says he is indebted to a New York paper for the illustrations of the blossoms and seed pods—and they are so poor that they excite the commiseration of the Club. He surely could not have got the yellow from the same source. A. G.

[The Yellow-wood or *Virgilia* owes so much of its attractiveness to the graceful sweep of its branches, the airy pendulous character of its flower clusters, and its charming and peculiar green, that it is difficult to give an idea of it by an engraving of a small part, as we found when we figured a flower-cluster in the *American Agriculturist* for Nov., 1875. Perhaps, taken for all in all, it is the

most beautiful of our native deciduous trees. Yet how few know this most desirable tree at all!—Ed.]

### A Garden Reel.

A convenient Reel for holding the line used in garden work, is presented in the accompanying engraving, from a sketch sent us by Mr. R. B. Kidder,

A CHEAP GARDEN REEL.

Columbia County, Wis. It can be made to suit the size and amount of cord. Mr. K., in making his, used a piece of inch oak, 4 inches wide and 3 feet long, sharpened at one end. A slot is cut in the top 2 inches wide and 12 inches deep, in which the reel is fastened. The shape of the pieces out of which the reel is made is shown at *a*. The cord is run through a hole one foot from the bottom of the standard, and secured at any place by looping the cord, or a small wooden pin may be used.

### The Most Fragrant Honeysuckle.

When we come across a desirable plant, or fruit, we are sometimes in doubt as to the best time for bringing it to the attention of our readers. If we describe the plant or fruit at the time of flowering or ripening, it is likely to be forgotten at the time of planting. On the other hand, if we defer the mention of such things until the planting season, they are very apt to be crowded aside altogether by things that have come up and demand immediate attention. As between the two we think that the best time to notice a plant is when it is in its perfection, whether of flower or fruit. It is a doubt that has occurred to us many times, and especially as we were, about the middle of April, enjoying the fragrance of *Lonicera fragrantissima*, the Most Fragrant Honeysuckle, and considering how we could best make known the merits of so valuable, and yet so unusual, a shrub. This Honeysuckle is one of the bush sorts, a native of the north of China, and though it was introduced over 30 years ago, about the same time with the Weigelas, the Forsythias, and others from the same country, it does not seem to have shared the popularity of its more showy companions. The bush grows 5 or 6 feet high, and as soon as spring fairly opens, its branches are thickly studded with little clusters of nearly white flowers, which appear before the leaves show themselves. The shrub can not be regarded as a very showy one, but when it comes to fragrance, we know of no shrub of its season that equals it in this respect. Not the heavy overpowering fragrance that we often meet with, but that delicate spring odor which some one has aptly called "woody," and which we find in such perfection in the Trailing Arbutus—satisfying in itself, and still more delightful in the memories it suggests. For the rest, the shrub is perfectly hardy, and requires no particular care, except perhaps a shortening here and there, when it tends to grow straggling. Let lovers of fine shrubs make a memorandum, to be referred to next planting time, to the effect that no collection of flowering shrubs can be regarded as complete without *Lonicera fragrantissima*.

### Another Tomato Trellis.

The above heading implies that we have already given other Tomato Trellises—and we have, a great many, from a rustic lattice-work of rough sticks up to permanent affairs, to be put away when not in use and last for several years. The fact that so many designs have been published, shows that a trellis of some kind is needed. If any of our readers have grown tomatoes without the use of something to support them, we advise them to not let the coming summer go by without a trial of one. Left to themselves, the tomato plants soon fall over, and a large share of the fruit rests upon the ground, often ripening unequally and soon decaying. Aside from

the question of neatness, and that in a garden is an important point, the vines, when trained, are more productive, and imperfect fruit may be cut out. For eating raw, there is no comparison between tomatoes ripened upon a trellis, and in the usual way, upon the ground. The fruit, being all in sight, can be gathered at the proper time, and there will be no loss from over-ripening, and no injury to the vines in gathering. Sometimes the tomato plants are trained to a single stake, but other than as a matter of amusement, this is not to be commended, as so much of the plant has to be cut away. It makes but little difference what kind of a trellis is used. Whatever can be most readily constructed will answer, whether of sticks, slats, or wires; it should be strung, as the weight to be supported is considerable; about four feet is a convenient height, though, if afforded support, the vines will grow much taller than this. Mr. Edmund Johnson, Winnebago Co., Ill., sends a sketch of the trellis here given; as his accompanying letter is an example of what such letters should be—to the point, giving all that is needed, and no more, we give it entire: "Our country gardens generally contain tomatoes, but they are allowed to grow along the ground without support, and thus the yield is very small. I send you a plan of the trellis that I use, and with very satisfactory results. The bases are pieces of 4 by 4 scantling, two feet long. A slanting hole is bored in each end, through which to drive a stout pin to keep the trellis in place. The upright pieces are 4 feet long, and 3 inches wide. The slats are 2 inches wide; 8 feet is a convenient length to make them. The manner of putting together may be seen in the diagram,"—which we may add was as clear as his letter is concise. Whatever kind of trellis is used, let the lower part

ANOTHER TOMATO TRELLIS.

be low enough to allow the plants to be tied to it before they fall down, and be sure to tie them before this happens, as after they have once fallen over it will be difficult to train them. Strips of cotton cloth are convenient to tie with. No other rule can be given than to tie the stems to the trellis where they seem to need it, and to cut away all the shoots that can not be tied without crowding.

### Cultivating Water Lilies.

We have several times suggested that those who are fond of the most beautiful Water Lily, or Pond Lily (*Nymphaea odorata*)—as "who is not"—can cultivate it with very little trouble. Those who have hesitated to make the attempt will be encouraged by the following account of its successful treatment, by Miss Ruckman, St. Joseph Co., Ind. Miss R. writes: "We have a half hoghead in our yard, which is sunk even with the ground. In the bottom is some of the soil taken from the bottom of a little lake where the Water Lilies grow. We put in several roots of the Lily, filled the barrel with water, and then awaited results. The next July we noticed seven small buds on the surface of the water; by the 1st of August, the surface of the tub was a mass of beauty, the large white Lilies being an attraction for the passers-by that could not be resisted. This was three years ago; each year there have been more flowers than in the previous summer. In the fall, we throw a little manure into the tank, place some boards over the top, and with this little bit of trouble increase the beauty of our experiment, which has been a success."

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### A Cocoanut Flower Bracket.

The hard shell of the cocoanut in the country where it grows is put to a number of important uses by the natives. To them the cocoanut tree furnishes most of the necessities, and many of the so-called luxuries of their simple and indolent existence. If we should enumerate the uses to which the shell is put it would be a long list, and possibly not without interest; but the point now is to call attention to its employment as a Bracket Pot for the growth of such plants as are usually seen in hanging baskets. The engraving gives an idea of

A NEAT COCOANUT PLANT BRACKET.

the end to be gained. The contents of the shell are removed by taking off a small portion at the top. A bracket board, that is, the back piece of an ordinary ornamental wall bracket, is then attached to it near the middle by means of three screws, which pass through the bracket and into the shell. With a hook or a brass-headed nail driven in a convenient place, the bracket can be hung up, and is ready to be stocked with suitable plants. The whole construction is simple, and with the plants in good order, there are few things in home decoration that are neater, easier to make, and more satisfactory than this same cocoanut shell bracket.

### Home Topics.

BY FAITH ROCHESTER.

#### Early Breakfasts.

I find macaroni an excellent thing for an early breakfast, the macaroni being boiled the previous day. I learned to use macaroni from the *American Agriculturist*, and it is now a very common dish in our family, and very popular too. The simplest method is the one most used by us. The macaroni is broken into short lengths and thrown into boiling water, boiled with a little salt until quite soft, then turned out into a little stone jar—(how handy these small jars are!) and set aside until next morning. I do not drain it (as the recipe says, and as I tried at first), but the liquor in which the macaroni is boiled forms a jelly when cool and dissolves again when heated in milk. In the morning, heat a pint of milk, a tablespoonful of butter, and a little salt and pepper, and turn the macaroni into it to heat, loosening it with your spoon as it heats. We cook about three-fourths of a pound at a time in this way, for a family of six. A little in a tea-cup in a school dinner pail gives great satisfaction. Stewed tomato is a good accompaniment.

#### Codfish Balls

are another convenient dish for early breakfast—the balls all made ready to fry on the previous day.

I speak of them now in order to say that I do not find it necessary to soak the fish over night when I boil it. Wash it well in three or four waters, put it over the fire with a good deal of cold water, let this heat pretty hot (boiling or not), and pour off this water and add more of as high temperature as that poured off. Boil very gently ten or fifteen minutes longer, but be sure that the fish is thoroughly boiled through. Mix the fish (well picked up) and the mashed potatoes while the potato is yet warm, seasoning with butter and (if the weather is not too warm) a little milk. Make into biscuit-shaped balls ready to fry. They should be fried in only just enough hot butter to brown well.

### The Baby Jumper.

About five years ago I told all about my baby's jumper, and a picture of the same appeared in the *American Agriculturist*. Another one has served the present baby, giving great enjoyment to all of the family. The first was attached to a long hickory "spring-pole." Perhaps there is nothing better, if you can fasten it securely to the ceiling and give it room to play up and down, passing through some kind of a strong staple placed a few feet from the end of the pole, which is fastened to the ceiling. This time we tried first a spiral bed spring, which we bought for five cents; it worked pretty well for some time and then was broken. A strong rubber band does very nicely; and may be fastened anywhere into the strap from the ceiling by which the jumper is suspended. Perhaps I had better tell once more, briefly, how the jumper is made. The seat in which the baby sits is a strong little jacket with a strap 3 inches wide fastened securely to the bottom of the waist behind, usually cut in the same piece. The waist of the jacket is buttoned together in front, the baby's skirts are laid smoothly, so as to cover and protect its legs like little trousers, and the strap attached to the waist passed between them and buttoned up to the front of the waist. This waist has no sleeves or arm-holes. Instead of meeting over the shoulders, it has four button-holes, two at each shoulder, one in front and one behind. Long straps, with strong buttons on the ends, button into these holes, two at each half arm-hole. These straps suspend the jacket seat, and are kept apart by being wound once around a barrel hoop and fastened there, half way up their length, leaving four even spaces on the hoop between them. The jacket may be as pretty as you like. Mine is made of strong, striped shirting, with a skirt 8 inches deep pleated around it—all bound with turkey-red. The hoop is wound with plain drab calico and turkey-red. The four straps, each about 2 feet long, are made of drab calico, quadruple in thickness. Above all this is the rubber strap and a small hemp rope—the whole is tied to a stout hook screwed through the plaster into a beam overhead.—[We reproduce the cut.]

A BABY JUMPER.

This jumper is an excellent baby tender. We put it up when baby was six months old, but did not use it much until the baby's limbs seemed strong enough to bear his weight, fearing crooked legs as a result. Soon it was just the exercise he needed for strengthening his limbs, and afterwards for helping him to learn to walk. He made unusually rapid progress in learning to run alone, but even after he had the run of the house, he delighted to be put into the jumper, and would go through his funny little gymnastics with great relish.

#### Little Girls' Underclothes.

A lady asks me how I make the underclothes "for girls eight or ten years old," just the ages I

have to work for at present. I have often written on the subject, and my testimony is still the same. Perhaps the lady is a new subscriber to the *American Agriculturist*, and I briefly give the method: A long-sleeved moderately high-necked strong cotton waist, buttoned behind, with whole drawers buttoned to the bottom of this waist, seems most reasonable for moderate weather. Two or three thin, low-necked sleeveless waists are useful for the very hottest weather. The drawers should be large and loose in the seat, the waist loose in every part. Skirts can be buttoned to the same waist by a separate row of buttons. Flannel underclothes are more suitable for winter than now.

### A Screen for the Bird Cage.

An ordinary Canary bird can make a great deal of work in proportion to its size, if no precautions are taken to keep his litter from being thrown out of the cage. Much of the food given to a caged bird consists of seeds with coarse hulls, and the seed-coats, after the bird has removed the kernel, are light and readily scattered to a considerable distance upon the carpet, table, or whatever may be below the hanging cage. To avoid the trouble of frequent sweeping and dusting, a screen of fine mosquito netting is now used by many lovers of caged pets. The netting—that of a pink color is perhaps the most attractive—is fastened around the cage, about midway between the top and bottom, by means of a ribbon, which can be easily untied when the cage is to be cleaned and the bird fed. The lower portion of the netting is brought together below the cage and also secured by a small tie. This latter does not need to be enclosed, as the netting opens down one side from the top, when the screen is easily removed. The accompanying engraving shows a cage thus decorated—for when neatly done it adds to the beauty of the whole. In the writer's home two birds are thus kept from throwing all sorts of litter upon the surrounding objects, and it is therefore from an actual experience that this cheap and neat screen is recommended for general use as a labor-saving contrivance.

SCREEN FOR BIRD CAGE.

### A Novel Pin-Cushion.

An old, broken lamp stand has often served a good purpose as the standard for a very useful, as well as ornamental pin-cushion. So, many other lit-

A NOVEL PIN-CUSHION.

tle household articles, that have lost their original usefulness by missing some of their parts, have been put to a new service by some change which the mind of the housewife readily suggests. The case in hand is the construction of a cushion for pins upon the back of a worn out hair brush. A neat cushion is put where the bristles were inserted, into which the pins can be set in a manner to sug-

gest the face of the brush when it was new. Such a brush pin-cushion is shown in the accompanying engraving. If further changes are desired a new back can be made by covering the old one with cloth, upon which a design in needlework can be made. A loop may be placed at the upper end, by means of which the cushion can be hung up in a convenient place. The binding around the cushion, and the other parts; in fact, the general make up will allow the exercise of a wide range of taste.

### The Sweet Potato Vine.

An easily managed, and at the same time most beautiful vine for the window is that of the common Sweet Potato. The rich, luxuriant foliage of a vigorous vine is not so much appreciated as it ought to be, partly because of the general impression, that a food-producing plant is not likely to be ornamental, hence the sweet potato is very little known as a beautiful climber. The treatment of the plant is very simple. A vase or any glass vessel, of convenient size to hold sufficient water, is all that is necessary. Select a good sound sweet potato, of a size that it will rest upon the edges of the vessel, while the lower end dips into the water. The plant being of tropical origin, a good degree of heat is required for its best development; a temperature of about 80 degrees is best. When once started, and given a plenty of light so soon as the leaves are putting forth, a handsome living, growing, window ornament may be produced. It is better to have a few strong and vigorous shoots than a mass of inferior ones; therefore if many shoots start, remove all but a few of the best. When the vines begin to grow well, they should be provided with a support, and trained entirely around the window, some of the shoots passing up one side, and some the other. A pretty ornament may be made by letting all shoots grow that will, and allow them to flow over the sides of the vase and hang down in a graceful manner. The chief care will be to keep up the regular supply of water which the plant will require in considerable quantity, as it is a vigorous grower, and to keep the leaves free of dust.

### How to Make a Flag.

"H. C. M.," Rockland Co., N. Y., who is probably inspired by the approach of the 4th of July and its associations, writes to ask how to make a flag, and adds that "it will be of interest to all your readers that love the American Flag." In the first place the material for a flag for service is *Bunting*, a thin fabric of wool, made especially for the purpose. This is light and strong, and bears the constant whipping by the wind better than any other material. Flags for certain uses are made of silk, and if for merely decorative purposes may be made of any desired stuff. The flag consists of two parts, the *Field* and the *Union*. According to the regulations, the depth of a flag should be  $\frac{1}{3}$  of its width. In ordinary usage, half as broad as long will come near enough. The depth of a flag is called its *head*, and its length, from the staff outward, the *fly*. The *Field* consists of 13 stripes of red and white, standing for the 13 original States, beginning at the top with red. The *Union* is in the upper corner next the staff. It is seven stripes deep, and four-tenths the length of the field; it is blue, with white stars, one for each State of the Union. We do not know if there is any regulation for the size of the stars. Formerly the small stars were grouped to form one large star on the blue field of the *Union*, but now the regulation is that they shall be "in equidistant horizontal and vertical lines." The better way to fix upon the size for the stars is to first make a paper pattern; cut the stars from paper, and change the size until the proportion seems right. Recollect that a star should always be five-pointed, with one point pointing upwards. We hope that these dimensions will help "H. C. M." and many others to make a handsome American Flag, and, "Long may it wave."

**Cooking Spinach and other Greens.**—Bacon and Greens, or "Gammon and Spinnidge," as the old writers have it, is a combination not to be

commended. In the old way of cooking greens with a piece of bacon or pork, not only is their delicacy of flavor lost—an important matter with Spinach—but the greens themselves become so thoroughly impregnated with fat as to be indigestible by most persons. The proper way with Spinach is, after washing and picking over carefully, to put it into a plenty of boiling water and allow it to cook, with the cover off, until tender; usually about half an hour. Then drain, chop fine, and place in a saucepan on the stove with a generous lump of butter until quite hot, then serve. Dandelions and other greens treated in this manner are greatly improved.

### A Balance Picture Holder.

It was several years ago that the modern view of matrimony (?) was illustrated in pasteboard needle-

A BALANCE PICTURE HOLDER.

work in so many parlors and sitting-rooms. A heart—human, it was understood—was placed in one scale pan, and a dime, or even an old-fashioned three-cent piece, in the other, of a balance that did not balance—the great heart being too little to overcome the weight and therefore importance of the coin. The illustration of the Balance Picture Holder may suggest that old household ornament. As far as being a balance goes, it is a deception, but looked at in the light of a neat picture holder, it is undoubtedly a pleasing success. In the picture balance there are no scale pans, and the arm of the balance is stationary. It may be made to move as in a regular balance, but it will not be found as satisfactory as when made immovable. The bottom may be made of any nice piece of wood, and worked into any shape desired. The same may be said of the standard and the arms. In the choice of pictures it will naturally suggest itself that they should, in a certain sense, be balanced. Some may prefer to put the extremes of age against each other, as the grey-haired and venerable grandparent, and the latest new comer into the family. Again, others may wish to show the power of contrast in the extremes of beauty; in fact, there are many views to take in the matter of striking a balance in an instrument like this, and that question must be settled—and it is not difficult—in its own way to suit each individual case.

**Around the House.**—The men folk are generally annoyed at the sight of untidiness when it is within the house, but are frequently oblivious to the same when it is out-of-doors. It does not matter whether the occupant of the house owns the grounds or not, the surroundings should always be neat and attractive. No one gets so much satisfaction from a clean door-yard as the person who passes through it in going out and coming in, at least twice a day, and in most cases many more—the one who lives in the house. It is a false principle to "clean up" for the sake of the impression it will make upon a chance comer or passer-by. If there is any time above all others when the door-yard should be "put to rights," that time is when the grass is starting, when the flower beds are to be arranged, and the work of the hands of man is followed by the first, vernal activities of nature. But all through the season, an hour now and then in the yard pays well. The great excuse is the lack of time; but the busiest man has hours that he can spend in making the surrounding of the

home look tidy; and the hours thus spent will be a recreation. It is the little matters of detail that count so much, the one way or the other, in the general appearance of a home. Be neat around as well as in the house for its own sake.

### Home-Made Feather Duster.

A Feather Duster is an article, the convenience of which every housewife appreciates, but it is often too expensive for many farmers to buy. For all such, some hints as to how a duster of equal utility and durability to a store one may be made at home from the feathers that would otherwise go to waste, may be useful. If beauty is not sought, any round stick of the proper size, such as the end of a broom handle, will serve for the handle of the brush; if one happens to have an old duster handle that can be used once more. With a saw make a series of grooves or deep notches in the lower end of the handle. By the aid of a hammer the lower portion of each quill should be so flattened as to pass into the grooves. As fast as the feathers are put in they should be tied with strong twine; and as the work proceeds glue should be added, that the feathers may be the more firmly fastened. In this way new rows of feathers, followed by the twine and glue, may be added, until the end is completely covered and the duster is of sufficient size, after which the finishing row of large feathers, selected for the purpose, is placed around the whole, and tightly bound with twine. Outside of the base of this last row of feathers, a neat strip of leather may be glued to both improve the appearance and render the feathers more secure. A brush thus made, will serve all the purposes of a purchased one, and if the work is carefully and thoroughly done, it may present as neat an appearance.

### A Cheap Glue Pot.

Glue would be much more largely used in the household when a break occurs in the furniture,

Fig. 1.—CHEAP GLUE POT.

and many other articles, if there was an easily worked glue pot at hand. A glue pot need not be expensive, as the one in figure 1 goes to show. Two tin fruit cans—one of the most common things to be found around the house now-a-days—a larger sized one for the water vessel, and a smaller one for the glue, is all that is necessary. The larger can is opened at one end, and the strips of tin turned back to make an opening, into which the smaller one fits closely, as shown in figure 1. The bails are added for convenience in handling, but are not essential to the make-up of the glue pot. A second form is shown in figure 2, in which the same sized cans are used, but the top is entirely removed from the larger one, and the glue can is held up from the bottom by a tripod of twisted wire, passing around the small can just below the rim, the ends resting on the upper edge of the water vessel. This is the extreme of simplicity in a glue pot; but at the same time it is complete. With the two cans and a bit of wire, the construction of this useful household affair is only a matter of a very few minutes. Let us have one.

Fig. 2.—GLUE POT WITH WIRE.

## BOYS &amp; GIRLS' COLUMNS.

## The Doctor's Talks.

Having built our kite, the next thing is to get it up. Before undertaking to fly a kite, be sure that your string is so wound that it will run off without any trouble or hitches; there is always danger of this with a ball of twine, therefore it is always best to have it wound upon a stick, and every boy knows how to do that. Having the tail so wound that it will not get tangled, we go to an open place, where there are no trees, telegraph wires, or anything else in the way, and we are ready

## TO FLY THE KITE.

Some boys make a great fuss about throwing up the kite, and think that success depends upon throwing it just at the right time. I don't know how it may be with other kites, but the bow-kite, the only one that I know much about, does not need to be thrown up. Spread out the tail in front of the kite, which has its point on the ground, letting one hold it upright. The string

Figure 1.

being securely tied to the belly-band, let off several yards of twine, and start and run against the wind, letting off string as you go. With a good kite and a fair breeze, it should go up without any fuss. Then the rest of the twine can be played out. If you run, holding the string from the kite, it will rise higher. If you go towards the kite, thus slackening the string, it will begin to fall.

## WHAT MAKES THE KITE GO UP?

We have seen how it goes up, and now wish to know what laws of motion are concerned. Here we must state a law that has not been given in these "Talks." It is this: When a body is acted upon by two equal forces, tending to carry it in different directions, it will take a course intermediate between the two. For example: if

Fig. 2.—ACTION OF WIND ON THE KITE.

a ball was struck by two different forces, as shown by the arrows, fig. 1, one tending to carry it from a to b, and the other from a to c, it would move from a to d, in a diagonal of a parallelogram, of which a, b, and a, c, are two sides. Now to apply this principle to the kite. In the first place, what forces are concerned in kite-flying? The wind you may think is the only force. But what happens when you go towards the kite? It falls, you know. It is plain that in this case the string is a force. We have then the wind, which tends to carry off the kite in one direction and the string that tends to hold it in another, and between the two forces the kite rises. In the diagram, figure 2, a kite is shown edgewise. The direction

Fig. 3.—AN ANCHOR FERRY.

of the wind is indicated by the arrow, W, and the restraining force of the string by S. The result of the two forces is in the direction of R. Thus we may see that

## THE KITE RISES IN THE AIR,

as the result of two forces acting upon it, the wind and the string. The motion resulting from two different forces is made useful in various ways, as is in some kinds of ferries, one of which is shown in figure 3. Here the boat is anchored by means of a long rope. If the boat stood square across the stream, it would remain at rest, but the rope is so attached that it turns obliquely to the stream, the force of which tending in one direction and the rope in the other, the boat takes a direction be-

tween the two, and is carried to the other side. I once crossed a ferry in Texas which operated on the same principle. A stout cable was stretched across the river from bank to bank. On this cable ran two pulleys, to which smaller ropes were attached, one of these ropes, being hitched to the front and the other to the rear end of a large flat-boat. The rope at the rear end being let out, to place the boat obliquely to the cable, the boat was, by the force of the current, slowly carried over to

Fig. 4.—ROPE AND FLAT-BOAT FERRY.

the other side. The working of such a ferry is shown in figure 4. The cable or strong wire, a, stretches between the two banks, the flat-boat or scow, b, is fastened by ropes to the pulleys, c, and d, which run along upon the cable. If the rope at one end is let out, so as to allow the boat to stand obliquely across the stream, the force of the current will carry it across. To return, the rear rope has only to be shortened and the other let out, to reverse the position, and the boat will go across in the other direction.

## The Baby Elephant.

We remember the first elephant we ever saw. Though we were but a boy of seven years, the day that we saw this great animal is fresh in the memory, and like the same event in the early life of thousands of children, it will never grow dim. There is something about an elephant that is impressive, and when you add to that the fact that a man sat on the elephant's tusks and put his head right into its mouth, the sight becomes so terribly new, that one does not forget it. But all great, big, strong elephants were once small—if elephants can be said to be small—and have their days of helpless infancy. Such a little baby elephant has recently been born in Philadelphia, and it is the first one that is known to have been born in the United States. This is not the native home of the elephant, and when brought here it is only for the purpose of helping to make up a show of wild animals. In the wilds of Africa, baby elephants are common; and they are usually taken from their wild state while quite young. The little new comer is the offspring of "Mandrie," the father elephant, who is 26 years old and weighs 8,000 pounds, and "Hebe," the mother, 23 years old and weighing 7,020 pounds. The calf at birth weighed 213½ pounds, and stood about three feet high. The birth of the elephant babe was the occasion of great excitement among the other animals of the menagerie, and the mother became so alarmed at the roaring of the lions and the noise of the tigers, etc., that she rolled over violently on the ground and did all in her power to protect her calf from supposed danger. She is so fond of her little one that she is extremely jealous of strangers, and will not allow her old pet dogs to come near her. The little elephant is very friendly to visitors, poking its slender trunk into pockets and up sleeves, to the delight of all. The other elephants of the herd caress it fondly, which flatters the proud mother of the first genuine baby elephant of the United States.

## Farming in Connecticut.

BY G. H. "AND THREE OTHER BOYS."

The great number of run-down or half-worked farms in old Connecticut now offered for sale would make it an inducement for any person who cares for some independence to try to become the owner of one, as many of them can be bought for less than the buildings on them are worth. Knowing this, we concluded to have a little actual experience in the matter. We have now been on this farm one year. We came from the City, and were rather obliged to come, so as to get something to live on, as we were out of business and about out of money. The man of whom we got the farm did but little on it, and many of the lots were full of weeds and briars. He had less than two acres planted, so the farm had not been made poor by plowing. Most of the land was in good condition, but needed working and seeding. We have tried a variety of crops. We plowed four acres once, but plowed it well, then harrowed and sowed it with buckwheat, harrowing in the seed, and we had fifty bushels, though we used no manure.

When we first commenced to plow in the spring for corn, we had a pair of horses that went so fast that we could hardly keep up with them, and so we plowed wide furrows to finish as soon as we could, and we had a big job in hoeing, but we dug and worked and got a good crop of corn. We use oxen now, as we like them better in this heavy soil than the horses, which are mostly used here. We raised some potatoes, enough to eat and for seed, and they are good ones. We planted in the furrow, as most of the farmers do here, that is, turn over the land, harrow, furrow out, drop in the furrow, and cover

with the plow. We had the best potatoes on turf land used in that way. This year we are going to ridge up some corn land, and try some potatoes in that way. We planted some peas, and had an abundance of fresh sweet ones to eat, not much like those had in the city. This winter we have got out a big lot of pea-brush, and are going to put in several bushels, as the boys intend to sell some (we mean three boys and one man). Before we came here a part of the garden had been mowed, the weeds were so big, but we manured it well, plowed deep, and planted in rows 3 feet apart, and then we cultivated and hoed until we had no weeds, but such a crop of vegetables as this old garden never raised before, enough for us and the neighbors, and such lettuce, cucumbers, tomatoes, beans, beets, sweet corn, parsnips, cabbage, etc., etc. We have enlarged the garden, and intend to plant some small fruits—strawberries, raspberries, etc., as it takes more time to hunt up the poor ones in the lots than it will to have them handy when wanted; and then the sight of them when growing is about as good as the eating. We are also going to set some small fruits in the field, and mean to have some to sell, as there are several good markets near, and the boys prove to be very good peddlers. On some turf land turned over and harrowed, we raised several hundred bushels of hard or Swedish turnips, some we sold, and we are now feeding the rest of them to the cattle, without cutting—it takes them longer to eat them, but they never get choked. We raised some cabbages and covered them in furrows in the field, and they kept well and sell quick, and we shall set a large piece of them this year. Our corn we cut up at the bottom, and it is fun for the boys to run it through the feed cutter. We started a manure heap after Harris' method, and have kept up a good heat all winter, and we have a big pile of it now for corn and other crops. We have sown a piece of winter wheat, and several acres of rye, and both look well. We have plowed since March came in, and shall try some fertilizers this year. We have a good flock of hens, and fresh eggs are very handy and good, both to eat and to exchange for groceries, and we are going to see if ninety acres of run-down land will not support three girls and four boys in old Connecticut.

## Our Puzzle-Box.

## NUMERICAL ENIGMA.

I am composed of 29 letters:  
My 24, 9, 18, 15, was an eminent Geologist.  
My 6, 17, 21, 2, was an ancient Patriarch.  
My 15, 4, 17, 28, is one of the heavenly orbs.  
My 25, 16, 9, is a woman's name.  
My 4, 27, 24, 7, was an ancient city of Asia Minor.  
My 24, 29, 23, 1, 21, is the name of a Greek letter.  
My 19, 5, 28, existing from eternity.  
My 23, 3, 26, 29, expresses a numeral.  
My 11, 10, 13, 1, 7, is a musical instrument.  
My 20, 21, 12, is an exclamation denoting surprise or joy.  
My 8 you will find in Joshua.  
My whole is a quotation from Dryden.

## HERA OLEA PHAROS.

## ANAGRAMS.

- |                      |                   |
|----------------------|-------------------|
| 1. Ruin at last.     | 6. Decent shrews. |
| 2. Shan't miss tape. | 7. Give a net.    |
| 3. Saul got lace.    | 8. Second credit. |
| 4. O yes! grunt.     | 9. Need my ax.    |
| 5. Do rub seven.     | 10. Very idle.    |

## CHANGES.

(Fill the following blanks with words pronounced alike, but of different meanings.—Example. She—the child to the store with one—Sent, cent.)

1. The—was found taking the—
2. The—walked back and forth on the—for exercise.
3. —very often decorates—
4. Her—tried to—her.
5. She—him—the child.
6. I can—loosen that—

## TRANSPPOSITIONS.

1. Transpose a fish into a verb.
2. A woman into a verb.
3. Some real estate into a verb.
4. A small animal into a verb.
5. An article of apparel into a verb.
6. An insect into a verb.

(Each of the six is a word of four letters.)

## ALPHABETICAL ARITHMETIC.

## ANIMALS ENIGMATICALLY EXPRESSED.

1. Part of a vessel, an exclamation and a title.
2. An animal, an article, and a mass of earth.
3. Part of the body, an unpleasant sensation, and an article.
4. Part of the body, a river, a kitchen utensil, an article, and a confession.
5. A vessel, an article, and the head of a river.
6. A title and an instrument.
7. A sign and a consonant.
8. A verb and a preposition.

## HALF SQUARE.

- |   |                        |
|---|------------------------|
| 1. A famous valley.                     | 5. A river in Liberia. |
| 2. Name of three towns in Italy.        | 6. A river in Europe.  |
| 3. To separate ( <i>vide Webster</i> ). | 7. A preposition.      |
| 4. A city in Portugal.                  | 8. A vowel. NEMO.      |

PUZZLE.

Take four-fifths of a dozen, and strange though it seem,  
'Tis enough to go all round the earth:  
Should you ask me its value, I'm sorry to say  
I really don't know what 'tis worth.

COUNTRIES IN GEORGIA ENIGMATICALLY EXPRESSED.

1. Something constantly sought, and a weight.
2. Something that one hears less of in February than in any other month, and part of an animal.
3. Something we have been recommended not to get into, and cunning.
4. A military term, and what many of us do not like to hear in the early morning.
5. The remark that sometimes follows the above disagreeable sound.
6. A vehicle and a list of names.
7. Part of a bird, and part of a river.
8. What none wish to be, and what all wish to do.

CONCEALED NAMES OF POETS.

1. Bob, row nearer to the shore.
2. I can't Mac. O keep still! there's a dnck.
3. It is a cow, perhaps.
4. Is this cottage for sale, I wonder?
5. Would you call that dog a yellow one?
6. Sit down on that log and wait for me.
7. Under the willow, Ella.
8. I shall stay until you return.

DECAPITATION.

Entire I am a certain movement of an army, behead me and you may sometimes see me under a bridge. Transpose the last and I burn. Transpose the whole and I delight; now behead me and I do mischief; once more behead me and you may see the very thing that did the damage; transpose this and see more harm.

SCATTERED SQUARE WORDS.

Find more than five square words in the well-known stanza.

"Little Bo-peep has lost her sheep  
And doesn't know where to find them;  
Let them alone, they're sure to come home,  
With all their tails behind them."

(From the letters in the first line you may make such words as POST, BALE, SORT, BEAT, and others; from the letters of the second line may be made other words of four letters, and so with the third and fourth lines. The first word of the "square" must be found in the first line of the stanza, the second word in the second line, the third word in the third line, and the fourth word in the fourth line. You must have, at least, two new words in each square.)

DOUBLE ACROSTIC.

1. A common exclamation.
  2. A mason's tool.
  3. Part of a ship.
  4. A precious stone.
  5. A French coin.
- The initials and finals name an American officer of the Revolutionary war. ISOLA.

CROSS-WORD.

My first is in coffee but not in tea,  
My next is in river but not in sea,  
My third is in finger but not in thumb,  
My fourth is in apple but not in plum,  
My fifth is in pantry but not in shelf,  
My sixth is in plunder but not in pelf,  
My seventh is in swoon but not in faint,  
My eighth is in varnish but not in paint,  
My ninth is in swim but not in float,  
My tenth is in ship but not in boat:  
Life were sad without my whole,  
It comforts many a weary soul.

ANSWERS TO PUZZLES IN THE APRIL NUMBER.

WORD-MAKING PUZZLE.—1. Add the letter U, to the word "engine," transpose into "genuine." 2. Shirt, thirst. 3. Dread, madder. 4. Love, novel. 5. Tale, valet. 6. Perusal, pleasure. 7. Cant, antic. 8. Suet, upset.

CROSS-WORD.—Frontispiece.

NUMERICAL ENIGMAS.—1. Threshing machine.—2. Local option.

PI.—The Royal Library of Paris contains two million volumes and objects of every description. The regular annual increase is twenty thousand. Nearly half a million books are French history, only twenty thousand English history; theology numbers 200,000, and in science and philosophy there are ninety thousand volumes. Printed, systematic catalogues furnished.

ILLUSTRATED REBUS, No. 475.—Experience increases our wisdom, but don't reduce our follies.

No. 477. Illustrated Rebus.—A truth that is easier to work out in a rebus like this than to keep constantly in view in every-day life.

A New Kind of Fishing.

Last month, the boys and girls will remember, we had a sort of a fish story, but we had but very little to say about the kinds of fish that were caught. In the accompanying picture—which we will imagine is a lake, or even an ocean—there are ten different kinds of fish. It is our work to help the readers catch these members of the finny tribe—in other words, to get them out by hook or crook, or any other way. Let us begin with the smallest, though not the least important, as many an old fisherman will say, and with it as a sort of bait—it is frequently used as such—try and catch the others. Again,

we should first capture this little fellow, because boys and girls are most accustomed to catching them, and that too in ponds too small for larger fish to live in.—No. 2 is a fish that is very fond of No. 1. It is scarcely necessary to remark that this fish is larger than the one we have already caught, and put upon the hook—so to speak—for the second. This fishing is on the principle that "big fish eat up the little ones." The one we are now after is olive-green on the back and nearly white on the underside, and is about a foot in length. The most common method of catching it is by trolling—the bait being kept in motion by a slow rowing of the boat. It is common, and the favorite fish for catching, in such large lakes as Champlain, George, etc. Lake Erie abounds in them.—No. 3 is a common freshwater fish, varying greatly in size, but usually not over a foot in length. It differs from most fish found in the same places, in having no scales; it has a head of great size as compared with the body, and peculiar soft horns around the mouth, and stiff spines on the fins that have hurt many a young fisherman. For catching this fish you need a great, big hit of bait, as a piece of meat, to which more than one fish may fasten itself and be brought in. They have very few bones, and are good eating besides.—No. 4 is a long slender fish, with a head and mouth in shape resembling that of a duck. It is too large to be caught by the ordinary method of fishing with a still hook baited with a worm. It is so fond of small fish that it will quickly take one even when a hook is fastened in the little fellow's back.—No. 5 so much resembles the one just mentioned that it is placed in the same family. Fishes, like other animals, have their first, second, and third consins, etc. No 5 is a noted fish; fine both for food and the sport there is in catching it. Some fish go in schools; this one keeps out of them, and is usually found alone. Other fish avoid it, for to be near it may mean sudden death. This fish is fond of shady places among the grass in fresh water streams. Trolling for this fish in the hatching season—the spring—is very exciting, and much loved by sporting fishers. A number of rules must be observed in safely landing one of these long, slender, greenish fish. When once safely on the hook, do not be in a hurry to get him out of the water.—No. 6 is probably the most common fish in the lakes, large and small, throughout the country. It is generally small, weighing from a half to three-quarters of a pound. The head is small and tapering; back olive-brown, sides belted with yellow, white underneath. The usual bait is the angle worm. They may be caught at all seasons of the year. On account of the spiny back fin, this fish is not so largely eaten by the "big fish."—No. 7, as the fishermen say, "don't bite," and if caught at all must be in a net or with a spear. It is the habit of this fish to run up small streams in the spring to spawn—that is, lay their eggs—and return to the lakes for the rest of the season. While in the shallow streams they are often speared in great numbers, especially at night, when a

torch or large lantern is used to furnish light.—No. 8 is a large fish, growing from one to over three feet in length, and from five to seventy-five pounds in weight. Its name is correspondingly long, and spelled in a dozen or more ways. Nos. 8 and 5 are much alike, and are to be caught in the same way. The Indians have told some wonderful stories about this fish, only equalled by those of the white-faced explorers of the northern lakes and rivers, where it abounds.—No. 9. We must go to the ocean, or at least, salt water, for this fish. The form of the face, which is somewhat smutty, is supposed to resemble that of a sheep, as also do the teeth. A clam, shell and all, is sometimes put on the hook as a bait for

A STRANGE-LOOKING LOT OF FISH TO CATCH.

this fish.—No. 10. A common small and exceedingly shy fish. The head is large, back greenish, sides silvery. Frequently taken through the ice in winter with hooks baited with cheese. The same name is unfortunately given to a number of kinds of fish.—No. 11 is found in the deep clear water of quiet streams. A very lively fish, moving in shoals or schools. It seldom exceeds a pound in weight. A "horned" variety is common in many streams, the head having spiny projections upon it.—No. 12. One of the oldest of the historical food fish, and one that is now being introduced into cultivation from Germany by our Government. No fish, excepting the gold fish, has been so extensively transported and grown in artificial ponds and lakes as this.—No. 13 is the last and the best of the list as a food fish. The flesh is reddish in color; the sides are sprinkled with spots. A large fish, from two to five feet in length, and inhabiting rivers, the Great Lakes and many smaller ones.

A Small Boy's Essay on Corn.

Some smart boy has been sitting up late nights when all the rest of the family thought him sound asleep and has produced an essay on corn, from which we take a few extracts: "Corns are of two kinds—vegetable and animal. Vegetable corns grow in rows; animal corn grows on toes.... It is said that gophers like corns; but persons having corns do not like to "go fur" if they can help it. Corns have kernels, and some Colonels have corns.... Another kind of corn is the acorn; this kind grows on oaks; but there is no *hoax* about the corn.... Folks that have corns sometimes send for the doctor, and if the doctor himself is corned, he probably wont do so well as if he isn't. The doctors say that corns are produced by tight hoots and shoes, which is probably the reason why, when a man is tight, they say he is corned." There is a considerable more of this essay, but we have only selected enough to show that the lad has a corner on the corn question, and has doubtless been feeding on corn cakes, corn dodgers, etc., or reading about that fabulous horse-like animal with a single horn—the unicorn.

### Shearing His First Sheep.

There are certain things in the life of the farmer boy that are events in his existence: places in his pathway up to manhood which, when passed, mark his progress. Just as in a school there are examinations through which the scholar must pass, so on the farm, there are practical tests to be applied to determine the ability and strength of the aspiring youth. In those places where wool-growing is an important feature of the farm, the shearing of his first sheep is an accomplishment to which the boy looks

together pleasant for the sheep; but when we remember what a relief it must be to them in the hot weather that follows, they are the gainers after all by the process of losing their wool. Sammy is standing in the foreground and is evidently in the last stages of an animated speech in favor of his own ability to shear a sheep—a statement which the other shearers are not quick to accept. With a flourish of the shears, which he has selected for his work, he loudly declares his intentions, and the older and wiser heads, seeing that persuasion is of no use, give each other the wink, and the youth, aspiring for honors

sweating and struggling of the still more unfortunate boy; but he has shown how matters shaped themselves in that final contest for freedom when the "victim" became the victor, and the young shearer literally took a back seat upon the floor. It was a hard struggle,—a battle,—in which the odds were against the boy; a conflict of muscle in which the weakest went to the wall, and the strongest to the open yard, dragging what little wool with him that the ill-guided shears had imperfectly clipped from his much-cut skin. The fourth and last scene speaks for itself. The men, with a sense of min-

FOUR SCENES IN AN IMPORTANT DAY OF A FARMER BOY'S LIFE.

forward as a sort of line which divides the youth from the man. Were it not for a seeming selfishness I would relate my first experience in this matter; but will step aside and let a near neighbor, Samuel Brown—"Sammy" we called him—be the hero of the story. Sammy was a boy with large ideas. He liked to do great things, or at least was fond of talking of the wonderful things he would do some day. I like all this in boys if it does not make them dizzy—does not make them think they are wiser and bigger than they really are—does not make them at a rather early age think what they do not know is not of any very great importance. Failures in all ages of life have their good lessons, but perhaps at no time do they teach so much as in youth. Sammy, to use a homely expression, was "growing very fast," and talked—and that boastfully, of his ability to do great things. And now for the sheep-shearing trials of Master Brown.

The artist has helped to make the matter plain with a series of four illustrations, showing as many different stages in the progress of the work—for it was work. In the upper left-hand corner we have a familiar scene on many a barn-floor in June. The shearers are at work busily taking the coat of a year's growth from the sheep, some of which may have become used to the uncomfortable situation through the experience of former years, while others find it a new and unenjoyable process through which they are forced to pass. Sheep-shearing, though done by the kindest and best shearers, is not al-

at the point of the shears, boastfully selects out his "victim" from the flock. The next scene lets us into the struggles which Master Brown experiences in bringing his sheep to the proper place upon the floor. Sheep, as well as other animals, are more powerful and less easily controlled sometimes than it would at first sight appear—and it is on this account that some of the most important instruction—the most useful knowledge—comes from personal contact—a grappling with the subject. The young shearer was, even in this stage of the shearing process, gaining a knowledge of the strength of sheep muscle, guided by a stubborn sheep's will, that he never had before. Under the circumstances it would not be expected that Sammy would receive any assistance from the men, so long as it was so loudly and boastfully disclaimed but a few moments before. From the third picture it is evident that the unwilling sheep was finally brought to a convenient place for shearing, and the process of unrobing the frightened animal was begun, doubtless under a number of serious difficulties which Samuel never before saw in their true light. "A looker on may see most of the game," but it is one thing to see and another to play the game. The process of sheep shearing had been observed so many times that the youth felt he knew it all, and had not been slow to make the feeling known. Of course the artist cannot represent and do full justice to the kicking and pulling and squirming on the part of the unfortunate sheep, and the

gled mirth and pity, appreciate the miserable state of mind and body of the beaten boy as he sits in sadness and silence, and watches without a word the easy stroke of the skilled shearer as he finishes the sheep that would not be sheared by a boy.

This account of Master Brown's trouble may seem hard on the boys; but there is a lesson in it, and that is just the reason why I tell it to the many boys—and it may not hurt the girls—of the *American Agriculturist* family. Sammy was made better by his unsuccessful attempt to shear a sheep before he was old enough to hold one. The experiment was a great success, because it taught him his strength and his place in the distribution of farm labor. I have been a boy, and, just like the great mass of them, and I know that when a boy gets above his work, he must come down, and the higher he gets the greater the fall must be. I could plow as well as the hired man until—the plow struck that stone. Don't I remember it well! and then I could do little else than cry. The desire to rise to the dignity and strength of manhood is worthy of only the highest praise—and every effort should point in that direction. It is only when the youth over-estimates his powers, and that to the annoyance of those of whom he might, but will not, learn, that the experience of Sammy will come. Sammy got a great deal that was of value to him out of his sheep shearing struggle. In some shape or other we all try to shear our first sheep.

UNCLE HAN.

**GOOD FERTILIZERS.**

We have again and again advised the farmers of the country to make a more liberal use of standard fertilizers if they would expect to increase their crops. Those who have experimented judiciously in this direction have seen no reason whatever to regret it. The foreign demand for our cereals seems likely to increase year by year. Business is recovering in all parts of the world, and, whether the nations are at peace or not, there will, in all probability, be a steadily increasing demand for our breadstuffs. In some sections of the country farmers are straining every nerve to increase their productions. They seek the best fertilizers, the best labor-saving machinery, and the best information they can get to help them in their special vocation; and during the next decade we predict that those who skillfully till the soil will do the best and safest business in the country. There are many kinds of good fertilizers—many kinds which are known to be exactly what are wanted by all farmers. We have recently taken special pains to inquire about the Michigan Carbon Works, at Detroit. This concern has an honorable standing and record. It is responsible and its statements are reliable. Its managers are well-known business men, and what they say they mean. We believe they are making a first-rate fertilizer, and that its general use would be a great benefit to the public. We advise all our readers who are interested in the matter to address the Company for further and full particulars in regard to what they specially offer.—*N. Y. Independent.*

**Organs and Pianos.**

The Hon. DANIEL F. BEATTY, of Washington, New Jersey, comes to the front with what he considers the greatest offer ever made on first-class Pianos and Organs. A fairer or more liberal offer was never made, for, if in any particular the description of instrument differs from the advertisement, Mayor BEATTY will take it back and pay all freight charges both ways. As an evidence of his immense popularity among those who know him best, we mention the fact of his re-election last week as Mayor of his city by an overwhelming majority.

Sold only in cans, by all Grocers.

ROYAL BAKING POWDER CO., New York.

## MINNESOTA CHIEF

## BEST THRESHER ON WHEELS

Is not a Vibrator nor an Apron Machine. Is wonderfully simple and admirably perfect in its threshing and separating qualities. Saves all the grain, and cleans it ready for market. Runs easily, is constructed durably, is finished beautifully, is the most economical, least expensive, and most satisfactory machine in the market. Will handle wet grain as well as dry. Has no equal in threshing flax and timothy, threshing and cleaning both as well and nearly as rapidly as wheat, and requires no change except the sieves. Has more square feet of separating and cleaning surface than any other machine made, and can not be overloaded. Is both over- and under-blast. Our CLOVER HULLING ATTACHMENT is new and very desirable. Does the work more rapidly and better than an exclusively Hulling Machine.

SEPARATORS of the various sizes fitted for Steam or Horse Power, as desired.  
An Improved Pitts Power, an Improved Woodbury Power, and the Elward Equalizing Power, all mounted on four wheels, are manufactured by us, and are not surpassed by any in the market.

We are also prepared to furnish first-class Portable Engines with our Separators.

For Price-List and Circulars, address  
**SEYMOUR, SABIN & CO.**  
Manufacturers, Stillwater, Minn.

# RIDGE'S FOOD for INFANTS AND INVALIDS

Has been manufactured in this country for ten years, and all orders for both the United States and Canada are filled by WOOLRICH & CO., whose name appears on every label. It is not, therefore, an imported article. Its use, however, for 20 years in England and 10 years in America shows its standard worth. Ridge's Food is NOT a medicine, but a highly nutritious and because a COOKED FOOD, easily assimilated. Take no new untried preparation because offered at a cheap price, when Ridge's Food can be obtained from all Druggists at 35 cents and upwards.

## A New Early Sweet Potato, EARLY GOLDEN.

This variety originated in Virginia a few years since, by an old cultivator of the Sweet Potato. It is a sport of the old **Early Red**, but said to be far superior to that variety in earliness, productiveness, color and quality. Slips planted May 10th, produced tubers large enough for the market July 25th. On account of its early maturity it is believed to be better adapted for cultivation in the Northern States than any other variety. In shape they are somewhat shorter than the ordinary varieties, of a golden yellow color, cook very dry, and are of superior flavor. Another valuable consideration in favor of this variety is, that they will grow on quite ordinary soil with but a slight coat of manure, and yielded a large crop the past season upon land that would not grow above fifteen bushels of corn to the acre. In good soil they will produce many specimens weighing three to five pounds each. It is also an excellent keeper. From what we can learn from those who have tested this variety, we think it will prove the most valuable in cultivation. Price of slips, with directions for planting, by mail, post-paid, 50 cents per dozen; \$1.25 for fifty; \$2.50 per hundred. By express at purchaser's expense, \$1.50 per hundred, \$12.50 per thousand.

B. K. BLISS & SONS, 34 Barclay St., N. Y.

ASK YOUR MERCHANT FOR

## LANDRETHS' GARDEN SEEDS.

They are NOT sent out all over the country to be sold on commission. They are NOT put up in Fancy Picture Papers, illustrating improbable vegetables. They are NOT to be found for sale in grog shops. They ARE grown by the Subscribers on their own farms in Pennsylvania, Virginia, New Jersey, and Wisconsin. They ARE put up in plain paper, at the lowest cost. The purchaser, therefore, pays for seed and not for fancy paper and printing. They ARE sold by respectable Merchants, Druggists, Grocers, etc., who buy them outright, because they know they will prove satisfactory to their customers. They ARE to be had in any quantity in papers—in ¼ lb. packages, in pints of Peas, Beans, and Corn, or in Bulk. If your Merchant does not keep them, send for Landreth's Rural Register and Almanac, containing catalogue and prices, and order them direct from headquarters.

DAVID LANDRETH & SONS, 21 and 23 South 6th St., Philadelphia, Pa.

[In writing to Landreth & Sons, please mention this paper.]

## LEWIS'S IMPROVED POPATO BUG EXTERMINATOR AND AGRICULTURAL SYRINGE.

Price, \$1.25, Post-paid. Polished Brass, \$1.75, Post-paid.

New Improvements for 1880. 10,000 sold in five months. One firm orders over 1,400 in three weeks. The fastest selling article in the U. S. My agents are making as high as \$22.50 in a single day. As a Potato Bug Exterminator I challenge the world for its equal in the saving of time, labor, or material. A light tap on handle discharges 3,000 to 5,000 fine drops on each hill as fast as you can walk. ¼ to ½ lb. of London Purple or Paris Green will give an acre three separate dressings. For syringing fruit trees infested with Canker Worms or insects of any kind, it has no equal. Agents make \$8 to \$15 per day anywhere. Read displayed advertisement in April No. of *Agriculturist* of Lewis's Combination Force Pump, on page 164. Price List, Testimonials, and Terms to Agents free on application to P. C. LEWIS, Catskill, N. Y.

## POTATO BUG. COTTON WORM. CANKER WORM.

THE BEST  
INSECTICIDE  
EVER USED.

## London Purple.

(Trade  
Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. If not obtainable of nearest dealer, send direct to sole manufacturers, HEMINGWAY'S LONDON PURPLE COMPANY (Limited), 60 Mark Lane, London, England. 90 Water Street, N. Y. P. O. address, Box 290.

A. R. WHITNEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have bld the Canker Worm a long forewell, and have done it with your LONDON PURPLE. We put in about three-fourths to one pound of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

**HEEBNER'S IMPROVED  
Level Tread Railway Horse Power  
with Patent Speed Regulator.**

Awarded the Medal at the Centennial, 1876.

Horses stand in the power with their feet in a natural position, relieving them of all strains and much of the fatigue occasioned by working on tread powers of the old style. Smooth shod horses or oxen work on them, walking at the rate of only 1 1/2 miles per hour. These Powers require less elevation, give more power, save the horses, and save money. Made with double or single gear, for one and two horses, and have the only successful Speed Regulator in the world.

**LITTLE GIANT THRESHER & CLEANER.**

The simplest, most durable, best and easiest working, and cheapest machine for threshing and cleaning all kinds of grain, also flax, clover, and timothy seeds now in use. It contains more good points than any other in use.

These Powers and Threshers are pronounced by all who use them to be, beyond a single doubt, the best in use. We own all the patents, and are the Sole Manufacturers, and have the machines in use all over the world. Send for illustrated catalogue. **HEEBNER & SONS,** Lansdale, Montgomery Co., Pa.

**BEST RESULT EVER OBTAINED.**

**FARMERS AND DEALERS,  
READ THIS!**

These cuts represent our 20 Steel-Tooth Horse-Rake, with Iron Hubs (or Locust Hubs bolted in oil) - 360 in use - and our Positive Force-Feed Grain, Seed, and Fertilizing Drill (which can be changed to sow any quantity while Drill is in motion), with Pin or Spring Hoes - 827 in use and giving satisfaction. All manufacturers say theirs are the best. All we ask is, send for Descriptive Circular and Price-List, which contains letters from persons using them. All are warranted. Hagerstown Agricultural Implement Mfg. Co. State where you saw Advertisement. Hagerstown, Md.

# THE HOMESTEAD, A HIGH-GRADE SUPERPHOSPHATE.

As manufacturers of Animal Charcoal, we have at our hands the most valuable material used in making fertilizers—viz., Bone Black Dust. This fertilizing substance contains eighty per cent. of phosphate of lime, against fifty-five per cent. contained in raw bones; and its well known value commands so high a price in the European markets that but very few manufacturers of fertilizers in this country use it. Although the HOMESTEAD Fertilizer costs us more to manufacture than if prepared of the materials generally used, we shall continue its present high standard, and place on the market a genuine, pure Bone Black Phosphate.

MICHIGAN CARBON WORKS, DETROIT, MICH.

Gentlemen:—Please notice the enclosed photograph of wheat cut from the same length of drill, seven inches apart—superphosphate and no superphosphate. Draw your own conclusions which is which. Of course, this is showing more difference than the field will average; but this shows what superphosphate will do on very poor soil. This was cut from a very poor spot, but each having the same chance, with the one exception. It was cut 13th of June. Shows the earliness of that fertilized. I have the best piece of barley in this section—100 lbs. superphosphate per acre sown on wheat stubble. The best farmers here are taking note of these things.

ALMONT, MICH., June 18th, 1879.

Very truly,

F. J. GROAT.

MEDINA, ORLEANS CO., N. Y., August 7th, 1879.

MICHIGAN CARBON WORKS:

Gentlemen:—Enclosed please find a photograph of some barley. This barley was grown on A. H. Poler's farm, four miles south of Medina, Orleans Co., N. Y.

I made a frame four feet square and set it in the standing grain on the day of its being cut. I then cut and gathered all that stood within the frame of each, where there was phosphate and where there was no phosphate. I let it lay in the sun one day to cure, then weighed each bundle as you see it on the photograph.

The phosphate was put down with the seed with a fertilizing drill, the teeth being six inches apart. These bundles were cut side by side, only six inches apart. The one on the left of the photograph had no phosphate, and weighed twelve ounces. The one on the right had one hundred and forty pounds of the Homestead Superphosphate to the acre, and weighed two pounds and fourteen ounces to the four feet square. This is correct.

A. H. Poler also experimented on corn, potatoes, and winter wheat, with as good results on each as on his barley. Of course he has not harvested his corn; but it stands sixteen inches higher than the rest of the corn and earing one-half better.

Yours, respectfully,

GEO. W. POLER.

## ACTUAL RESULT AT OUR SEED-FARM ON LETTUCE SEED.

Homestead produced.....	583 lbs. per acre.	116 lbs. of lettuce seed, at \$1.25.....	\$145 00
Where none was used.....	467 "	560 lbs. of Homestead, at \$40 per ton.....	11 20
Difference favor of Homestead.....	116 "	Actual profit per acre.....	\$133 80

D. M. FERRY & CO.

Send for Circulars, giving full reports of results and all particulars in regard to use.

In places where we have no authorized agent a barrel of 200 pounds will be sent on receipt of \$4.

## ODORLESS FLORALIS.

Prepared expressly for Lawns, Flower Gardens, Pot and House Plants.

DIRECTIONS.—Use three tablespoonfuls of the manure to a gallon of water. Steep twelve hours before using, and keep well stirred while being applied. Do not apply oftener than once in two weeks.

PRICES, Box containing 10 lbs.....	\$1 00
25 lbs.....	2 00
50 lbs.....	4 00

Sent anywhere in the United States or Canada, by express or freight, on receipt of cash orders.

JONES PAT.  
DRILL POINTS

Fit all drill bits, run level, out from bottom furrows, cover with molasses soil, and instead of crowding the seed into narrow rows but one inch in width, soatter it 3 1/4, 4, and 5 inches; the plants thus standing wider apart, have more ROOM TO STOOD, derive more nourishment from the soil, become more vigorous, and produce better developed average heads.

As ye sow, so shall ye reap.

Send for Illustrated Circular with Testimonials to J. A. JONES, Wilmington, Del.

## A REPLANTER

Is offered for planting Corn and other large seed, combining simplicity, utility, and accuracy. It will plant in all soils. Boys can do good work with it, and are delighted to get to use one. Price only \$3, delivered at your nearest station or express office. Agents wanted.

THOS. B. McCONAUGHEY, Newark, Delaware.

## WELL BORING,

ARTESIAN WELL DRILLING & MINERAL PROSPECTING MACHINE, and how to use, is fully illustrated, explained and highly recommended by the "American Agriculturist" in the November Number 1879, Page 465. Sent for it. Portable, low priced, worked by man, horse or steam power. Needed by farmers in every county. Good business for Winter or Summer, and very profitable. Can get good wells in earth or rock anywhere. We want the names of men that need wells. Send for illustrated price-list and terms to Agents. Address, Pierce Well Excavator Co., 29 Rose Street, New York, U. S. A.

## Champion of the World! THE CHAMPION GRAIN DRILL

With or without Fertilizer, or Grass Seeder Attachments, or Gum Spring Hoes.

It has a perfect force feed Grain Distributor that will sow accurately all kinds of grain without the least injury to the seed. The most perfect Force Feed Grass Seed Distributors in the market. Fertilizer attachment can be relied upon to sow all kinds of commercial manures whether dry or damp in any desired quantity. Draft Light, Construction Simple, but durable. Liberal discount to cash customers. Send for descriptive circular.

JOHNSON, GERE & TRUMAN,  
Owego, Tioga Co., N. Y.

## METROPOLITAN AGRICULTURAL WORKS.

Farm Implements and Fertilizers.

No. 1 Peruvian Guano: Standard. No. 1 Peruvian, Lobos brand—Russell Coe's Superphosphate of Lime.

Complete Manures, Metropolitan Fertilizer, Pure Ground Bone. Sold at lowest trade price, by the ton or cargo. Send for 1880 Pamphlet.

H. B. GRIFFING,  
No. 70 Cortlandt Street,  
New York City.

## THE BEST ALWAYS PAYS.

In order to be able to meet the increasing demand for PURE PREMIUM BONE, we have removed our entire establishment from Salem to Alliance, O., where we shall be pleased to see and hear from all who want the best fertilizer that the market affords. Address all communications for the purchase of Premium Bone or sale of raw stock to LEWIS SCHILLING, Pres't, Excelsior Fertilizing Co., Alliance, O.

## W. S. BLUNT'S Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE "MEDAL OF SUPERIORITY." The highest award of the American Institute for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be removed, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern DEEP WELL non-freezing FIRE PUMP.

Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1 1/4-inch to 4-inch suction pipe.

Send for circulars to

Batavia, Ill.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 220.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the *American Agriculturist* are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist* (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Home Made Root Cutter.**—"L. B." In the March number for last year we gave a description, with illustrations, of a cheap and easily constructed cutter for preparing roots for farm animals.

**Osage Orange a Rapid Grower.**—A specimen of Osage Orange planted by Dr. Darlington at West Chester, has been recently cut down. At one foot from the ground, the body of the tree, about 50 years old, was 10 feet 3 inches in circumference.

**Liquid Manure.**—The amount of fertilizing material in the urine of animals equals that contained in the solid excrement, but is in a form that may be very readily lost. The *Urea* is the ingredient of chief value—a quite complex nitrogenous substance which is easily decomposed into Carbonate of Ammonia, and then escapes into the atmosphere. Whenever there is a pungent odor of ammonia from a manure heap, or tank in which liquid manure is stored, there is a loss of valuable manure taking place, and it should be arrested by using some absorbent as plaster, manure, or litter of any kind.

**Asparagus in Wet Soil.**—"S. T." Marion, Ind., writes to Peter Henderson, asking a question on Asparagus culture. Thinking that the reply may be of use to many others, Mr. H. sends it for the Basket. "His land is 'rich alluvial deposit, which at certain seasons of the year is covered by water for three days at a time,' and he wishes to know if such land 'would be suitable to grow Asparagus or other crops.' We think not, the land being covered with water for three days becomes so completely saturated that the roots are actually in water for twice or thrice that time, and no plant other than an aquatic could so long endure inundation without injury. These bottom lands on the margins of streams, are usually most fertile, and if by diking or banking, the water can be kept off, no land is better fitted for garden crops."

**"I Do Earnestly Desire Information,"** is the ending of a letter which we *could* have answered on a postal card, and it would have reached the writer in time to be of use. But the writer, though he so strongly expresses his "desire for information," takes very good care that we shall not give it to him, for he signs himself "Young Gardener." He has cut us off from reaching him by mail, and as for the paper, we have a rule not to answer anonymous letters. If those who write us do not sign their names, the letter goes into the waste-basket, unless, as in the present case, we make use of it as a text to remind new subscribers of this rule. A number who have lately asked a variety of questions, and have not given their names, should, if the answers are of importance to them, repeat the questions over their own signatures. It so happens that one at least of "Young Gardener's" queries is answered in this paper, the same having been asked by one who gave his name. It should be understood that we do not publish a name when we know that the writer prefers that we should not do so; this he could have indicated by placing his real name after or below the signature "Young Gardener."

**Another Veteran Peach Tree.**—C. Thompson Adams, Norfolk Co., Mass., sends an account of a Peach-tree that he had just cut down. "The tree was on the land when my father bought it in 1840. It came up from a hole made by lightning, at the foot of a large Oak that was struck and killed, the seed having probably been planted by a squirrel. For the past 10 years it has borne more or less fruit, though previous to that time it bore but little." Forty years and over is old for a peach tree.

**Hay Caps** are usually made of common unbleached cotton, and it is best to buy that which is fully a yard wide, as it, when cut into squares, makes the most economical caps of the most handy shape and size. The raw edges should be hemmed, which can be done very rapidly on a machine; at the same time the corners should be turned up two or three inches, thus making a fold in which a cord may be inserted. This cord should form a loop, by means of which the cap can be pinned down with short wooden pins provided for the purpose. These caps are of great value, as a large quantity of hay may be secured against a sudden storm at just that time when a rain is so damaging to the curing hay.

**Liquid Manure.**—To answer several inquiries at once, we may say that either horse, cow, sheep, or hen-manure may be used, and no definite rule can be given beyond the caution to not use it too strong. Where there is a provision for saving the drainage from stables, this may be used upon the garden if sufficiently diluted. A cask or barrel may be prepared by putting some straw in the bottom and half or two-thirds filling the barrel with horse, cow, or sheep-manure. This is to serve as a leach, pouring water in at the top and draining off the manure "lye" at the bottom. The old direction to dilute this to "the color of boarding-house tea," is perhaps as definite as any. Where guano is used, one pound to five gallons of water is abundantly strong, and with the best Peruvian Guano, twice the quantity of water to a pound would be safer. In the use of liquid manure, some precautions are to be observed. It is not to be applied to the foliage, but to the root of the plants. In dry weather, draw away the surface soil, apply the manure, and when this has soaked in return the soil. This is to prevent the baking of the wet soil and forming a crust. A better way to accomplish this is to place a mulch of straw, litter, or chips, on the surface around the plants. The manure may be applied through this mulch. In a dry time, do not use the liquid manure unless the plants can be kept watered as needed until rain falls again.

**Swedish or Alsike Clover.**—Several have written us from different parts of Pennsylvania, stating that a person was selling seeds of the Swedish Clover, and asking our opinion about it. None of these reported any thing beyond the bare fact, and as our "opinion" of the matter would depend altogether upon what was represented in regard to the clover, it was difficult to reply. There is no special reason why one should go about selling this seed any more than he should that of Hungarian Grass, Buckwheat, or any other seed kept by all the regular dealers, and we were curious to know what the vender claimed for this clover. At last Mr. S. Stouffer, of Huntingdon Co., has sent us a circular, and a remarkable document it is. We are told that the clover "takes its name from the Alsikean districts of Stockholm,"—which is about like saying that Buckwheat gets its name from Bucks Co. in Rhode Island. We are told that the clover is "extensively cultivated by the leading agriculturists of Great Britain," which is not true. We read in the circular of "Its Great Hardiness, for no winter can kill it, capable of resisting the extremes of drouth and frost, and the certainty of the plant when other varieties fail." The latest authority on this point that occurs to us is Mr. Root, who is, as was Mr. Quinby before him, much interested in this clover as a honey-producing plant,

and would gladly have it succeed. In his recent "Bee-Keeping," he says: "But experiments indicate that in dry sandy soils it is not permanent, and will not survive the second winter." Our correspondent sends us a sample of the seed to know "if it is genuine;" we can only say that it looks like the seed of Alsike Clover, but when Mr. Vosburg says "Sold only by" himself, he tells that which an inquiry at any seed store will prove to be as much a work of his vivid imagination as some of the other remarkable statements in his very remarkable circular. We are told that the peddler sold his seed at the rate of \$45 per bushel. As this is just two and a half times the retail price of the regular dealers, it is not difficult to see why he should peddle. We have frequently cautioned our readers that new and valuable seeds and plants were not bawled about the country by peddlers; such things are first to be had of the regular dealers. This clover is not at all new, nor is it, in this country, especially valuable.

**"Making Roads."**—The repair of roads is much more costly than it should be because the system—if it can be called a system—of their construction is extremely faulty. An earth road, rounded up in the center, can seldom be more than passable for at least a third of the year. The repairing of such a road usually consists in adding more earth, and this is usually done in the worst season of the year. It is not to be expected that American roads, constructed so rapidly, can be made like the hard, smooth, and lasting road beds of older countries, but the work that is done on them, from year to year, should be of such a kind as to make an approach to a perfect road. Broken stone is the best material for road-making, and as this is a common material, it should be much more generally employed. Just how this stone is to be used and where, are matters which each town or road district must decide. Whatever is done, let it be done well, and make a finish of the work as far as it goes. The most used and worst part of the thoroughfare should have the first attention. A little good road made each year will in time see the whole in a satisfactory shape.

**Grinding Tools.**—The value of an edge-tool depends very largely upon the cutting edge, or, in other words, upon the kind and frequency of the grinding. An instrument that is "as dull as a hoe," ought not to be very dull. The ease with which weeds may be cut with a hoe kept sharp by occasional grinding, compared with the trouble given by a hoe that is never sharpened, ought to lead to the practice of keeping them sharp. We know that turning the grindstone is back-aching work, but when a few minutes of it makes the reaper or mower go much easier for several hours, the grinding should not be neglected. It is a saving of labor to keep the tools sharp; it pays in every possible way.

**The Buckwheat Crop** is the last crop of the season, and in the latitude of New York, is sown the last of this month or early in July. It is frequently a "filling crop"—that is, sown in some place where some early crop has failed. It is often used to kill weeds, as it is a rank grower, and completely shades the ground, thus acting as a "cleansing crop." As a means of bringing up the fertility of poor or partly exhausted soil, buckwheat is specially good, as it is a close and pretty deep feeder, and will produce a large crop of green material that may be plowed under, thus increasing the organic matter and thereby enriching the soil. The quantity of seed to be sown is from two to three pecks per acre.

**Michigan Timber.**—The "Peninsula State" leads all others in the production of timber, but at its present rate, its valuable wood-land must be diminishing very rapidly. The "crop" for 1879 is reported as follows:

Saginaw District.....	736,106,000 feet.
Huron Shore District.....	410,646,000 "
Interior Mills.....	518,670,000 "
Lake Michigan Mills.....	1,338,127,000 "
Total.....	3,003,549,000 "

**Australian Competition.**—The shipment of meat from Australia to England has been successful, and that great island-continent, with its 7,000,000 head of cattle, enters the contest for supremacy in the British Meat Market. In this matter, we, as a nation, are deeply interested, because any competitor like this, leads to questions that are vital to the meat producers of our great grazing interior. Can the growing of cattle be cheapened? This is a question which is the natural outgrowth of rivalry; and this will lead to an improvement in the kind of animals; the production of more and better meat. All this is natural, and leads to good results. The matter of transportation will not be behind other interests, and a reduction of the present high rates will follow. Not the least among the benefits, will be a serious handling of the question of the necessities of the middlemen, with a reduction of the number of hands through which stock now must pass, each one taking a portion that ought to go by good rights to the producer, or at least, be divided between him, and those who consume the meat. There are a number of important prob-

lems involved in our present production of meat, that a healthy rivalry will lead us to solve, to the best good of all concerned. With our large, vast grazing country, and a proper adjustment of transportation rates, a better class of animals, etc., we may hope to compete with Australia or any other country, in supplying meat to England.

**Dipping Sheep.**—The effect of a Dip is to free the sheep from all external parasites, as ticks, scab, etc., and skin diseases, the causes of some of which are not fully understood. A Dip of 12 lbs. of Tobacco and 6 lbs. of Flowers of Sulphur, to 50 gallons of water, is one that has been so generally used, that it can be recommended. Some add to this a little Concentrated Lye, a pound or so, and about the same quantity of Arsenic. If arsenic is used, proper caution should be exercised, and the poisonous nature of the mixture kept in mind. The sheep are to be dipped while the mixture is warm. Those who have had experience claim that the dip of tobacco and sulphur will do all that can be accomplished by the use of arsenic. It may not be generally understood that sulphur does not dissolve in the Dip; hence, in order that each sheep may get its share, the mixture while in use, should be frequently stirred up from the bottom, and the sulphur be thoroughly diffused through the liquid.

**Coal-Oil Barrels.**—In answer to an inquiry as to the best method of preparing kerosene and other such barrels, so that they may be used for cider, etc. "C. K. C., Beloit, Wis., writes: "Take one head out of the kerosene barrel, start a fire in the bottom, and put a bushel of dry straw, or long shavings, in to keep it burning long enough to draw the kerosene out of the wood; let it burn a few minutes, and just before the wood commences to burn, turn the open end to the ground, and the flame will be smothered. Use the barrels for water a couple of weeks, put the head in again, and they are ready for cider, or anything else one chooses to put into them. The barrels will be worth double the price of common ones." C. K. C. omits to state that the other head that is removed should also have the same treatment and be burned, etc. Another correspondent, "R. P. T., Cedar Rapids, Iowa, recommends to first burn thoroughly, then scrape, and scald them with hot water, then fill them up with clay, letting them stand with the clay in them for 4 or 5 days." R. P. T. omits to say what kind of clay, whether dry or moist. As it is to act as an absorbent, we suppose it should be dry. Would not dry earth answer as well as clay?... W. Scott, Kankekee Co., Ill., says that he has cleaned fish barrels and made them sweet enough for packing butter by half filling the barrel with lye and rolling it occasionally; when the lye has taken up all the grease, it is emptied out and the barrel filled with water and allowed to stand for several days. We doubt if this method would be of much utility with coal-oil barrels. "C. A. E., Bridgeport, Mich., says if the barrel is so placed that the steam from the exhaust pipe of a steam engine will pass through it, that no smell of oil will be perceived after a few weeks. He also says that they will become sweet if used for a few months as rain-water barrels.

**Pipes for Conveying Water.**—"I wish to bring water from a spring to my house (or barn), what kind of a pipe shall I use?"—is in brief the substance of several letters that have come of late; though some express fears of lead pipe, others ask if iron pipe can be used with safety, and so on. Probably in regard to cost, ease of laying, etc., lead pipe is cheapest, so far as out-laying goes, but it may be dear in the end, as in some cases its use has caused serious illness. For all soft water, lead pipe should be avoided, but for hard water it may be, even for domestic purposes, used without danger. Hard water soon forms a coating over the interior of the pipe, and the water no longer acts upon it. Where water is flowing continuously through the pipe, or where the precaution is taken to first draw off all the water that has stood for some hours in the pipe—a precaution so easy that it should always be taken—there is little or no danger in the use of lead for any but the softest water. Iron pipe is quite safe; it soon becomes coated with the oxide of iron, and if some of this be taken into the system no harm can follow. "Galvanized iron," so called, is iron coated with a film of zinc, to protect it from the action of the water. This it does effectively, but the zinc itself is acted upon by the water, and is more or less dissolved by it, hence galvanized iron pipes should not be used for water. Tin-lined lead pipe would be excellent were it not for the fact that tin is very brittle, and is liable to crack; when this takes place the lead is dissolved more rapidly than were it not so coated, and as there is always danger from this source, such pipes are not advisable. Of course there can be no objection to glazed earthenware pipes, but they can not be used where there is much pressure, and the cases in which they are available are comparatively few. On the whole, for soft water, iron is the best material, while for waters too "hard" for washing, lead may be used with entire safety if the precaution above mentioned be observed.

### The Prize Essays on Keeping One Cow.

The prizes offered in the February number of the *American Agriculturist* brought to the Editors more than seventy (73) essays. Over half of them thoughtfully and well written. They were submitted to two gentlemen in entire ignorance of who their authors were, and they awarded the prizes as follows: 1st prize, \$50, to "Buttercup," Mrs. G. BOURNOR, House of Commons P. O., Ottawa, Canada; 2d prize, to "Doctor," W. S. BATTLES, Girard, Pa.; 3d prize, to "Mobile," Geo. G. DUFFLES, Mobile, Ala.

### Insects and Force Pumps.

A few years ago we knew not the Potato Bug, and the makers of pumps and hand-water engines of all kinds could make their squirts to clean carriages, wash windows, put out fires, and do various other feats in hydraulics without regard to bug killing. Now a pump that does not provide for the potato is not complete. Such was our thought as we unpacked the parts of "Lewis' Combination Force Pump." It must not be thought from this that the pump is complicated—as it requires but a simple change to convert a regular force pump, with its short hose, into a garden syringe. Another slight change—and there you are—a Paris-green or London-purple—the potato bugs are provided for, and the combination is complete. The thing is a perfect arsenal of water guns, each serviceable in its way, and made for use rather than show.

### "The Complete Home."

If an inexperienced house-keeper wishes to know how to cook a particular dish, there is a whole library of works ready to help her. But cooking is not the only department in the management of which a young house-keeper, and for that matter, one who is not young, needs advice, and it is very seldom that it can be had save of some other house-keeper of wider experience. But every mother of a family has not a friend at hand to whom she can go in her doubts and perplexities concerning the various matters of home management; and the work entitled "The Complete Home" is intended to be an adviser in not only what relates to the material comfort of the home, but with regard to what we may term the morals of the household. In all that relates to—what old fashioned people call "the bringing up of children"—its teachings appear to be eminently sound and useful, and it is a work that may prove a comfort and a help to many a mother.

### Milk in New Jersey.

New Jersey has excellent laws regarding the sale of milk; that State has a way of executing her laws (and sometimes the people who don't observe them) and the State Board of Health are taking measures to put them in force. Dr. Wm. K. Newton, Paterson, has been appointed State Inspector of Milk and circulars are sent out informing people of the requirements of the laws. The case is well covered by this statement—"Milk may be defined as pure when it comes from a healthy cow and when nothing is taken from or added to it." Those who deal in any other kind of milk are liable to both fine and imprisonment. The State Inspector wishes to obtain samples of milk from diseased cows, especially from cases of pleuropneumonia—they may be sent to his office in Paterson.

### American Cutlery.

It is not many years ago that it was rather a severe test of one's patriotism to purchase an American knife, the chances being greatly against it being of serviceable quality. At present American knives are among the best. We are glad to know that in making scissors great progress has been made by our manufacturers. Large scissors or shears have long been produced of excellent quality, but small, delicately formed and highly finished scissors were until recently imported. There is no need to look abroad for scissors, to judge from a sample of the manufacture of Maher & Grosh, Toledo, Ohio, recently placed on trial. Of course one can not tell how they will stand the wear of months, but for present excellence, fine form and finish, they are exceedingly creditable and full of promise.

### "The" Authority.

The street signs of New York are always interesting and especially so just after the May movings. A rural paper published in the City of New York celebrates its removal with a perfect eruption of signs. One of these reads "The American Horticultural Authority." "The Authority" is good, and it was well to put it on the sign, as it might not be discovered by reading the paper.

### To Measure Corn in the Crib.

"R. A. S." Douglass Co., Kansas, writes: "Get the contents of the crib or bin to be measured, by multiplying the length and breadth, and this product by the height, all in feet. Multiply the product by 4, and cut off the right hand figure. For example, the crib is 10 by 16 feet, and 8 feet high,  $10 \times 16 \times 8 = 1280$ . Multiply the product 1280 by 4, makes 5120, and cut off one figure, giving 512, the number of bushels of corn. Should the corn be settled very tight, having been in the crib for six months or more, I multi-

ply by 4½ instead of 4. I have bought and sold thousands of bushels by this method, and know it to be correct. Place this in your 'Boiled down' list, recommending it to be pasted on the barn door of all corn raisers." This is certainly a quick method.

### The Hydrangea "Thomas Hogg."

No longer ago than October, 1876, we published an engraving of this Hydrangea, and described it as one of the most important of recent novelties. This spring we find it very generally for sale by the street vendors of plants who offer it among verbenas, geraniums, and other plants at the stands near the markets. This shows two things: 1st, that the plant is of easy propagation, and 2d, that it itself possesses merits which will make it popular. Both of these are true of this; but we always regret to see persons buy plants forced into flower.

### Prof. A. R. Ledoux.

We mentioned some months ago that Doctor Ledoux had resigned his position as chemist to the N. Carolina State Board of Agriculture. A few days ago we had the pleasure of a call from him and learned that he had already established himself in the city as a chemist and proposes to give special attention to investigations relating to agriculture.

### Night Soil.

This name was given to the contents of privies, because the emptying of them is largely done at night. Its bad odor is the chief objection to its use upon the garden, and this is enough to keep it from being employed, unless it is first deodorized. Liquid from the privy vault may be used, by making holes here and there in the garden soil, filling them with the liquid manure, and replacing the earth after that has soaked away. We have raised very fine tomatoes in this manner.

### Big Peruvian Corn.

"C. O.," Iowa. This corn is by no means new to this country; we figured some of the enormous kernels in June, 1866, and it was tried by several of our friends at that time. We observe that it is again introduced, and farmers are again asked to try it. There is no doubt but what it will grow—indeed, that is the trouble with it, it doesn't stop growing. Frost will come and find it still growing without even stopping to make a tassel. The variety is entirely unsuited to our climate. It would perhaps come to perfection in the southernmost States, and if it were worth while, one might by selection in a few years establish a variety that would be earlier in its ripening. We have not seen the ear, but are told that it is not only not large in proportion to the kernel, but is really quite small. Supposing it to be a different species from the common corn *Zea Mays*, some European botanist has called it *Zea Macroserma*; big-seeded *Zea*. It is often called "Cuzco corn."

### Granular Butter.

To those who have inquired in reference to the production of butter in the granular form, described in an article in April last, we would say that the peculiar condition is not due to the kind of churn that may be used. Just as good granular butter may be produced in the "Blanchard," or any other churn with a revolving dasher, as in any form of oscillating churn, it all depends upon stopping at just the right time, and that is, when the granules have formed, and before they have been compacted into a uniform mass, as they will be, if the motion of the churn be continued.

### Fighting the White-Grub.

No pest of our farms and gardens is more destructive than the White-Grub. It is especially mischievous for the reason that we know nothing of its presence until it has done its work. Operating underground, and out of sight, but little can be done to destroy it. We have several times suggested that the only effective method of attack is when it is in the perfect or beetle state. Many are not aware that the parent of the White-Grub is the so-called "May-Bug," "June-Bug," or "Dor-Bug," as it is variously called, and which often makes its way into the house in the evening, attracted by the light, where it makes its presence known by a great deal of bustle and noise as it bounces about in a headlong manner. The few insects that come into the house give but little idea of the great numbers that are doing mischief elsewhere. In each locality the beetles are especially abundant once in three years, and were the cultivators of a neighborhood to unite, in the destruction of the beetles, the White-Grub would do comparatively little damage. Some beetles appear every year, but the great crop is once in three years. As every female lays about 200 eggs, the importance of killing her before she has a chance to provide for that number of grubs will be seen. W. C. Stiles, Jr., Wood Co., West Va., has been acting upon our suggestion, and sends an account of his success. Mr. S. uses a "Tubular Lantern" set in a discarded milk pan, an inch or two of water is placed in the pan, and a layer of coal oil (kerosene) is put upon the water. The first night he tried two traps like this, he caught 199 beetles; the second night he caught over 500, and proposes to continue their use so long as any are taken. Of course any

good lantern will answer as well as the one he used. Unlike many others, this is destructive in its beetle state, feeding usually on the leaves of trees, especially the cherry-tree. In the years of their abundance, the trees in which they take refuge should be found, and in the morning, while they are torpid, the insects should be shaken off, caught upon sheets, scalded, and fed to pigs. Several pitfalls have been taken in this manner in a single morning. The much abused crow does good work in destroying the grubs. We know of a case in which they caught the grubs that were at work upon the grass of a lawn. We have no doubt that when the crow is accused of destroying the young corn, it is merely after the grubs that attack the plant. The skunk is known to destroy great numbers of the beetles.

### Beautiful Pansies.

No doubt that many who have seen the colored plate illustrating Pansies, and published by Messrs. B. K. Bliss & Sons with their Catalogue, have supposed that the artist had exercised his imagination, both as to size, and the strange combinations of colors. So far from this being the case, the flowers are, if anything, rather below the real size, and as to colors, it would be impossible to conceive of any artificial colors more brilliant, or more strangely contrasted, than they are in the flowers produced by the remarkable strain of seeds secured by Messrs. Bliss & Sons. Some of the blooms are as near black as it is possible for a flower to be, and of a velvety texture of great richness.

### Potatoes to Bermuda.

In conversation with a friend who was familiar with the Bermuda trade, we asked him what the steamers principally took on their return trip. The reply was—"Everything eatable, including potatoes." As "Bermuda Potatoes" are one of the principal exports from the Island, we supposed that the potatoes sent there were to be used for seed, but were informed that they were to be eaten—the planters finding it more profitable to sell their potatoes, than to eat them, as the price of a barrel of Bermudas, will buy several barrels of those from the States, and pay freight besides.

### Bitter Milk.

"Mrs. A. N.," Jefferson, Tex., finds that her cows eat "Dog-fennel," and that the milk is on that account disagreeably bitter. We do not know of any help after the plant has been eaten. If any reader does, we hope it will be made known.

### Millet Seed for Chickens.

"J. T.," Baltimore, Md., writes, that "those who know nothing of feeding Millet seed to young chickens, have something to learn. It does away with the customary slop attending the mixing of meal, and the seed may be swallowed by the smallest fowl. I use it altogether." There are now several things called "Millet," in cultivation; we suppose that our correspondent has reference to one of the *Setarias*, known as "Golden," "Mammoth," "Bengal," and "Hungarian Millet," and closely related to Hungarian Grass.

### Pond Lily Culture.

"C. W." and others. We have not published any directions. A tub of some kind, some garden soil and water, are all the requirements. A tub may be made from a portion of a cask, and if desired it may be sunk in the ground. Place in the tub good soil enough for the roots, perhaps a quarter full will be sufficient; put in the plant; it is not necessary to plant it, merely pressing the stem into the soil will answer. The big affair which passes for the root is really the stem, which lays along the bottom of the pond. One side of this produces roots which take a strong hold of the soil, as every one who has tried to get up one knows, while buds producing the leaves and flowers are on the upper side. When the tub is filled with water, no further care is required during summer, except to supply water as it may be needed, as it is not likely that the rains will make up the loss by evaporation. Unless the tub can be so protected that it will not freeze solid, it should be removed to the cellar at the approach of cold water. Only enough water need be left in the tub when it is moved, than will be needed to keep the soil moist.

### Mowing Machines.

It is estimated that 150,000 of these labor-saving machines are annually manufactured. There are 35,000,000 acres of meadow land in the United States, and the thought of mowing all this by the old method of the scythe, is enough to make one's hack ache. Thanks to the inventive genius of a few men, that there is an easy and inexpensive, as well as rapid way, by using the mowing machines, many kinds of which are models of neatness and simplicity.

### Food for Cattle Good for Fowls.

A while ago we had something to say about Weston's Food for Cattle, stating it to be a mixture of well known condiments and tonics, prepared in a convenient form for use. We have since been assured of its utility as a food for fowls and young chicks. From our knowledge of its composition, and of its effects upon horses and cattle, we should expect good results from giving it to fowls.

# NICHOLS, SHEPARD & CO. Battle Creek, Mich.

Established  
in 1843.

ORIGINAL AND ONLY GENUINE

## "VIBRATOR"

Threshing Machinery and Portable  
and Traction Engines.

THE STANDARD of excellence throughout the Grain-  
Raising World.

MATCHLESS for Grain-Saving, Time-Saving, Perfect  
Cleaning, Rapid and Thorough Work, and all other Seeds.  
INCOMPARABLE in Quality of Material, Perfection  
of Parts, Thorough Workmanship, Elegant Finish, and  
Beauty of Model.

MARVELOUS for vastly superior work in all kinds of  
Grain, and universally known as the only successful Thresher  
in Flax, Timothy, Clover, and all other Seeds.  
simple, using less than one half the usual gears and belts.

ASTONISHINGLY DURABLE and wonderfully  
PORTABLE, TRACTION, and STRAW-BURNING STEAM-ENGINES, with special features of Power,  
Durability, Safety Economy, and Beauty entirely unknown in other makes. Steam-Power Outfits and Steam-Power  
Separators a specialty. Four sizes of Separators, from 6 to 12 horse-power; also 2 styles Improved Mounted Horse-Powers.  
32 Years of Prosperous and Continuous Business by this house, without change of name, location, or manage-  
ment, furnishes a strong guarantee for superior goods and honorable dealing.

**CAUTION!** The wonderful success and popularity of  
our "Vibrator" Machinery has driven other  
machines to the wall; hence various makers are now attempt-  
ing to build and palm off inferior and mongrel imitations of  
our famous goods.

### BE NOT DECEIVED

by such experimental and worthless machinery. If you buy  
at all, get the "ORIGINAL" and the "GENUINE"  
from us.

For full particulars call on our dealers, or write  
to us for Illustrated Circulars, which we mail free. Address  
NICHOLS, SHEPARD & CO., Battle Creek, Mich.

## ORIGINAL AND ONLY GENUINE BUFFALO PITTS

THE STANDARD of Threshing-Machine  
excellence throughout the Grain-Growing World.  
SELDOM EQUALLED. Never excelled.  
NOTORIOUS as a fast yet thorough thrasher,  
perfect cleaner, and entire saver of all kinds and  
conditions of grains and flax and timothy seeds.  
NOTORIOUS as the only machine that is a  
success in all kinds of threshing and a  
failure in none.  
NOTORIOUS as the best built, most durable, and  
handsomest of the Threshing-Machine Tribe.  
STEAM THRESHERS a specialty. Their  
superiority, it can be said with truth, is acknowledged  
throughout the world.

**CAUTION** To Agents as well as Threshers-  
men. Be sure you get the genuine  
Buffalo Pitts, made only at THE PITTS AGRICULTURAL  
WORKS, Buffalo, N. Y. It is said that  
other manufacturers are using the name "Buffalo  
Pitts" on their make of Threshing Machines.  
This Unintentional Compliment to the  
great reputation of the only genuine Buffalo Pitts,  
by use of its title to sell inferior machines, is flatter-  
ing to the "Buffalo Pitts." But Agents and  
Threshers must not be deceived, nor hold the  
genuine Buffalo Pitts responsible for the faults  
of its bastard nameake. For Catalogues and Price-  
Lists of the genuine Buffalo Pitts, address

THE PITTS AGRICULTURAL WORKS,  
Buffalo, N. Y., U. S. A.

## Union Railway Horse Power.

Also, manufacturers of the PREMIUM FARM GRIST MILL.

THRESHERS AND  
SEPARATORS.These Powers are  
GUARANTEED

to produce more Power  
with  
LESS ELEVATION  
than any other Railway  
Power. Send for descriptive

## CHICAGO SCREW PULVERIZER.

### Does Pulverization pay?

ANILENE, KANSAS, Nov. 10, 1879.  
I seeded 3,400 acres of wheat with these machines... The  
stand of wheat is now the best I have ever seen on new  
land.  
R. J. WEYMES, Trustee.

DANVILLE, ILL., Dec. 4, 1876.  
This year I harvested, on 190 acres, 6,100 bushels of wheat.  
... In my opinion the Screw Pulverizer increased the crop  
one-third over what I could have got by any other method.  
D. G. MOORE.

Send for pamphlet with cuts, and over sixty letters from  
men who have the machine. Address,

Chicago Scraper & Ditcher Co.,  
34 METROPOLITAN BLOCK, CHICAGO, ILL.

## ZIMMERMAN

FRUIT AND VEGETABLE

DRYER &amp; BAKE OVEN

Over 11,000 in use.

THE BEST in the Market.

Made entirely of Galvanized Iron

AGENTS WANTED.

Send for Circular Address

ZIMMERMAN FRUIT DRYER CO.,  
Cincinnati, Ohio.

## EVAPORATING FRUIT.

SENT FREE Treatise on improved methods. Tables, yields,  
prices, profits, and general statistics.  
AMOS STOFFER, Chambersburg, Pa.

## THE FERGUSON BUREAU CREAMERY.

Surpasses all others in quantity and quality of butter made. It secures matured and ripened cream, which makes butter of the best texture, flavor, and of unequalled keeping quality. It excludes flies, dust and odors; is constantly at the correct temperature (58° to 60°); has room for the cream and butter, and saves three-fourths the labor. It can be used with either ice or water, and both summer and winter.

**THE FERGUSON CONCUSSION CHURN** is the best. It combines scientific principles with the best labor saving devices. No floats or paddles. Brings the butter in granular form, and secures the largest yield. Before buying any other Churn or Creamer; or any pans, or cans, send for large illustrated circular to **THE FERGUSON MFG CO., Burlington, Vt.** Reliable Agents Wanted.

### HOUSE-KEEPERS, ATTENTION!

#### THE GLOBE WASHBOARD AND THE IMPROVED UNION CHURN

Are the best in the world. Neither have any equals. Over 600,000 **Globe Washboards** sold in 1879. No more sore hands or torn clothes on inferior washboards. Buy it and try it. The **Improved Union Churn** is the perfect butter-maker. Easier and quicker than by any others. One trial will convince any one of the fact. Send for circulars with full details. Liberal terms to dealers.

**UNION MANF'G CO., Toledo, Ohio.**

### BUTTER WORKER.

The most effective, simple and convenient yet invented. **Works 30 lbs. in less than 5 minutes, thoroughly working out buttermilk and mixing in the salt. AGENTS WANTED.** Send for Circular.

**A. H. REID, 6 N. Eighteenth St., Philadelphia, Pa.**

### BUTTER WORKER.

#### Lilly's Patent.

Won First Premium at the American Institute Fair, New York, in 1878; at the Fair of the Penn. State Agricultural Society in 1879; at the Dairyman's Fair at Delhi, N. Y., in 1879, and at County Fairs innumerable. Acknowledged to be the **only self-feeding and reliable machine in the market.** Descriptive circular sent free.

**C. H. R. TRIEBEL, 316 Race St., Phila., Pa.**

#### Rectangular and Square BOX CHURNS

**Cheapest and Best.** No inside fixtures, and always reliable. Six sizes of each kind made. Three sizes of the **Lezer Butter Worker** made. Best material used, and every Churn and Butter Worker warranted exactly as represented. One Churn at wholesale where we have no agent. Send Postal for Circulars. **AGENTS WANTED.**

**CORNISH & CURTIS, Fort Atkinson, Wis.**

**25 Shades ready for Brush. The Best MIXED PAINTS in Market.** Also Barn, Bridge, and Fence Paints. Send for circular.

**CHICAGO WHITE LEAD & OIL CO.,**  
Cor. Green and Fulton Sts., Chicago, Ill.  
**E. W. BLATCHFORD Pres. C. F. GATES, Treas.**

### THOMAS' OSTEOPHONE

**FOR THE DEAF**—Sold by principal Druggists and Stationers. Mailed on receipt of price, by Manufacturers. Circulars free. **A. C. FARLEY & CO., Philadelphia, Pa.**

### THE Hartford Compressed Air PUMP.

**Water Driven to any Height and Distance by Compressed Air.**

Country Houses Supplied Cheaply and Certainly for Bath Rooms, Water Closets, Hot and Cold Water Faucets, etc.

**Plenty of Fresh Water for Stock on Farms.** The best Pump for irrigating, supplying Railroad Tanks, and for Mining purposes.

For Circular and Price-list address

**EZRA BROOKS,**

**Sec. and Gen. Manager of The Hartford Compressed Air Pump Co.**  
Hartford, Conn., U. S. A.

**Spiral Spring Singletrees.** Secured by two patents. Price \$3.50 per pair. Send for a pair, or send stamp for illustrated circular and full description. Local agents wanted. Territory for sale. **F. R. WILLSON & SONS, Columbus, Ohio.**

### AGENTS WANTED to Sell the NEW BOOK, FARMING FOR PROFIT

**TELLS HOW TO** Cultivate all the Farm Crops in the Best Manner; Breed, Feed and Care for Stock; Grow Fruit; Manage Farm Business; Make Happy Homes, and **How to Make Money on the Farm.** Every Farmer should have a copy. **860 Pages. 140 Illustrations.** Send for circulars to **J. C. McCURDY & CO., Philadelphia, Pa.**

### NEW BOOKS

**Published by D. LOTHROP & CO.**

#### THE SPARE MINUTE SERIES.

Elegant cloth binding. \$1.00 each. Free of postage. "The significance of the name of the new series is seen from the fact that 'Thoughts that Breathe,' for instance, has 300 pages, and contains 273 separately numbered and independent extracts. Thus a person can read one or more of these at a time, and put the book down without breaking the train of thought."

#### THOUGHTS THAT BREATHE.

Comprising selections from DEAN STANLEY. With an Introduction by PHILLIPS BROOKS.

#### CHEERFUL WORDS.

Comprising selections from GEORGE MACDONALD. With an Introduction by JAMES T. FIELDS.

#### THE NIGHT OF RIGHT.

Comprising selections from the works of the Right Hon. Wm. E. GLADSTONE. With an Introduction by Gov. LONG.

**India.** By Mrs. FANNIE ROPER FRUNG. 100 full page Illustrations. Price \$1.50. 1st Vol. of Lothrop's Library of Entertaining History to be followed by Histories of Egypt, Scandinavia, Spain, Switzerland, and Russia.

**Pushing Ahead; or, Big Brother Dave.** By Edward A. Rand. 16mo. Illustrated. \$1.25.

**Our Street.** By Mrs. S. R. GRAHAM CLARKE, Author of Yeatsie Walton. 16mo. Illustrated. \$1.50.

**Wide-Awake.** 20 cts. per No. \$2.00 per year. Pure and Healthy in tone. Edited for real boys and girls.

**Babyland.** 50 cts. per year. Absolutely without a rival.

**Boston: D. LOTHROP & CO., Publishers.**

### 100 SPECIAL PREMIUMS.

A selected list of over 100 important works in the several branches of Science offered **free** with new subscriptions to the

Light, Strong and Simple.

M. E. Bungler & Co.,  
Indianapolis, Ind.  
MAKERS.

Send for Price and Illustrated Circular.

## HORSE MANURE

PACKED IN BALES.

Under Letters Patent Granted to JAMES B. ARCHER. This method of preparation by compressing and baling the Horse Stable Manure direct from the stables of the city, is for fertilizing purposes, in compact bale of about five hundred pounds weight. By this process all the air is excluded and all the valuable properties of the manure are retained in a moist state, saturated with all the organic and inorganic substances, in a soluble form, until applied to the soil.

### THIS VALUABLE FERTILIZER

Places it within the reach of all farmers, horticulturists and others using fertilizers in a form convenient for cheap transportation and handling. Can be shipped upon cars or steamboats without injury to other freight, and in the hold of vessels without damage to the timbers. All bales will have the patent stamped on the frames. Orders for this manure are solicited and prompt attention given thereto.

Packing Yard and Shipping Depot, 42d and 43d Sts., East River, New York.  
J. B. ARCHER, Manager.

Address After long experience this has been proved to be the only proper way of baling and handling the manure. Application for right to bale in places throughout the United States to be made to J. B. ARCHER, Patentee, Room 12, 64 College Place, New York.

## Perfect Milk Pail

Price \$2.25.

Preserves Milk from all dirt, and from the odors of the stable, of the yard, and of the milker, which give the so-called animal odors. A seat while milking; holds 14 qts.; can not be stepped in, nor kicked over by the cow; the milk is strained before entering it. Address DAILY SUPPLY CO., New York, P.O. Box 116.

## PRACTICAL CAMELLIA CULTURE

For the Florist, Amateur, &c.

Price two dollars per copy, postage paid. Address ROBERT J. HALLIDAY, Florist, Baltimore. Send two-cent stamp for circular giving Contents of Book, and Endorsements of Camellia Growers.

## BAT AND TRAP.

As here represented, the articles necessary to play this game are one bat, one ball, and the trap. Any number of persons can engage in the game, from one to five on a side, and it can be played by ladies and gentlemen, or girls and boys. It can be played on the lawn, meadow, or any place where baseball, lawn tennis, or croquet

are played. The ground need not be smooth as for croquet. It is very fascinating, and has as much variety as any other popular game. Rules accompany each game, and they are easily learned.

Price, \$2.00.

Expressage to be paid by the Recipient.

ORANGE JUDD CO., 245 Broadway, New York.

# Summer Out-Door Games and Toys.

## LAWN TENNIS.

Until within the past few months, this Game was imported entirely, but now we are manufacturing sets in this country in such quantity, that we are able to sell for \$10.00 a com-

plete set that equals, if not excels, such as last year were sold for \$18 to \$20.

## Special Offer for 30 Days Only.

In order to introduce our American Sets into every City, Town, and Village in the United States, we offer, if ordered at once, the regular \$10.00 Set, which is complete, for \$9.00. Expressage to be paid by the recipient.

This set is handsomely gotten up and will last for years.—Remember, orders must be sent in at once.

ORANGE JUDD COMPANY, 245 Broadway, New York.

## COLUMBIA BICYCLE.

Bicycle riding is unsurpassed as a method of travelling, whether for speed, sport, or the renewal of health. No horse can compare with the bicycle for endurance, no other pastime is half so fascinating, and the exercise is recommended by the medical profession as being most conducive to health. Appleyard rode 100 miles in 7 hours, over a common turnpike road, and Waller has accomplished 1,400 miles in 6 days. Send 3c. stamp for 24-page catalogue, containing price lists and full information, or 10c. for catalogue and copy of "The Bicycling World."

THE POPE MFG CO.,  
No. 101 Summer St.,  
Boston, Mass.

B. W. PAYNE & SONS, CORNING, N. Y.

ESTABLISHED 1840. Patent Spark-Arresting Engines, mounted and on skids. Vertical Engines with wrot' boilers. Eureka Safety powers with Sectional boilers—can't be exploded. All with Automatic Cut-Offs. From \$150 to \$2,000. Send for Circular. State where you saw this.

WM. D. ANDREWS & BRO.,

## TUBE WELLS.

235 BROADWAY,

Opposite Post-Office, NEW YORK.

W. S. BLUNT'S

## Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE "MEDAL OF SUPERIORITY." The highest award of the American Institute for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability.

They can be immediately changed from lift to force pumps, and the air chamber can be revolved, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern DEEP WELL non-freezing FIRE PUMP. Also, Blunt's Sand Vacuum Chambers. A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1½-inch to 4-inch suction pipe.

Send for circulars to NASON MFG CO., 71 Fulton and 71 Beekman St. New York.

New England Agency, A. M. MORTON & CO., 25 Washington St., Boston, Mass.

Pacific Coast Agency, Dunham, Carrigan & Co., San Francisco, Cal.

### HIRES

IMPROVED ROOT BEER PACKAGE, 25 CTS. Makes five gallons of a delicious and sparkling beverage—wholesome and temperate. Sold by druggists, or sent by mail on receipt of 25 cts. Address, CHAS. E. HIRES, Manufacturer, 215 Market Street, Philadelphia, Pa.

# THE MAPES MANURES,

Especially Adapted for Wheat, Rye, and Permanent Grass.

These Complete Manures are prepared for heavy as well as light soils, and are found, after a long and practical experience throughout the northern and seaboard States, to fully equal the best stable manure, not only in product of grain, but also in the permanent effects on grass. The hay is of superior quality, more nutritious, and freer from weeds.

The cost, including labor of application, is only about one-half as compared with purchased stable manure.

Send postal for descriptive pamphlet and price list. Address

THE MAPES FORMULA & PERUVIAN GUANO CO., 158 Front St., New York.

A FULL ASSORTMENT OF PURE BONE, PERUVIAN GUANO, AND CHEMICALS.

NEW SERIES—No. 402.

A COOL, SHADY COW PASTURE. — Drawn and Engraved Expressly for the American Agriculturist.

There is an impression possessing the minds of many farmers that there is only one profitable place for a forest tree, and that is the "wood lot." To them a tree in a pasture is "a plant out of place," and therefore a weed, to be rooted out and destroyed. But there are good reasons why the cleared fields should not be entirely destitute of trees. In the first place, they add greatly to the appearance of the whole farm, making it more attractive, and therefore of greater value. A shady pasture is a comfort to the farm stock that is kept within its boundaries. The domestic animals—the horses, the cows, the sheep, and pigs, which we as farmers care for and feed, because they provide for our wants, are more than mere machines for our thoughtless running—they are living creatures possessing capacities for pleasure and pain, and therefore demand at our hands the kindest treatment. But there is another side to this question. The well

reared-for animal is the one that pays the best returns. Looked at with the practical dollars and cents view, that care which best provides for the wants of the animal is the most remunerative. Every blow received by a cow at the hands of thoughtless help, costs the owner of the cow something either in milk, or flesh, or both. All pain does not result from violence, and discomfort is as unprofitable in its results as actual pain. If one doubts the discomfort of exposure to the sun of a mid-summer day in an open, unshaded field, it will not require a long experience to convince him of it. Man is not the only creature capable of being sun-struck. A few years ago one of the writer's cows, in the full flow of milk, fell off at once to almost nothing. Investigation showed that she had been thoughtlessly exposed all day in a pasture where there was no tree or other shade. In our plea for shade in pastures we are well assured that abun-

dant returns will be found in the shade alone. But beyond this there is the tree, itself. In planting a grove it should be remembered that a White Ash will make as good shade and more valuable timber than Soft Maple. There are often low places in a pasture-field in which a spring may be located, or through which a small stream flows—places where trees will grow vigorously, and still be out of the way should the pasture be turned into a grain field, because the land is not tillable. It is in just such secluded and shady places as these that the farm stock love to escape from the intolerable heat of the sun's rays on many a mid-summer mid-day. The accompanying engraving: "A Cool, Shady Cow Pasture" is a pleasing one, because it is the outgrowth of a true conception of what a pasture should be: namely, comfort and satisfaction to the dumb but appreciative animals, and pleasure and profit to the thoughtful, kind-hearted owner of the farm and the stock.

## AMERICAN AGRICULTURIST.

NEW YORK, JULY, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

**Harvesting.**—The work of harvesting the wheat, oats, barley, etc., should be begun before the grain is fully ripe, as it is less liable to shrink and is therefore heavier and of a better quality. The straw is worth more if the crop is cut before the grain is fully ripe, an important consideration on every farm where straw is used for fodder. There is also less waste from the shelling of the grain in the process of harvesting; while the work can be performed without that hurry and rush which must be experienced if the grain is left until later. A delay from unfavorable weather does not involve a serious loss when the work is begun early, and in season.

**Corn.**—The cultivator should be kept going, to both kill the weeds and pulverize the soil and keep it damp and mellow. When the corn gets large the horse should be muzzled that he may not be nibbling at the corn and forget his work among the abundant green fodder. It should be kept in mind that the work of cultivating the corn crop has a great influence upon the growth of the crops that are to follow. The full returns for work done in the corn field are not all in when the corn is gathered, a point that should always be borne in mind.

**Summer Fallow.**—A summer fallow was formerly considered the proper preparation for a wheat crop. Where hoed crops are introduced into a regular rotation of crops, the desired cleaning of the land and pulverization of the soil may be effected without resorting to the more expensive method of fallowing. This being the case, the increase in the amount of roots grown will diminish the acreage devoted to summer fallow.

**Wheat.**—When wheat follows oats in the rotation, the stubble may be stirred with a cultivator to give the scattered oats a chance to sprout before plowing for the wheat crop. If the oat crop is harvested before the grain is fully ripe, as it should be, there is less need of this precaution.

**Turnips.**—Flat turnips may be sown this month for early feeding. Although not so profitable for the main crop as Swedes or mangels, they have their

place in a farm system that economizes labor by its uniform distribution throughout the season. Flat turnips are not to be recommended as feed for cows giving milk, but they are valuable for sheep, especially in making a gradual change from grass to the dry feed of winter.

**Fodder Corn** may be sown in succession as directed in June, as late as the middle of this month. The small quick growing varieties are to be preferred. The latter part of July and through the month of August, in our northern climate, the pastures get dry in average seasons, so that a modified soiling system is desirable to secure a full supply of feed for the cows and horses.

**Fodder Crops** in the shape of Millet or Hungarian grass may be sown during the early part of this month, and as the hay crop is very light in many places, a fodder crop of some kind will be more than usually important this year. The soil for a fodder crop should either be naturally rich or made so by manuring, or it will not pay to prepare it for any of these quick growing grains which have but little time in which to make their growth, and must get to a good size in order to be profitable.

**Meadows.**—As soon as may be after the hay is gathered give the meadows a good top dressing of fine manure. This will produce a thick bottom growth to shade the ground and prevent the soil from drying up and injuring the roots of the grasses.

**Water Supply.**—An abundant supply of pure water is essential to keep animals in a healthy and thriving condition. The importance of pure water for animals is too often overlooked. Impure water is a fruitful source of disease to animals as well as man, and the quality of milk is impaired when cows are compelled to drink at stagnant pools.

**Cows** giving milk should not be allowed to fall off in quantity from insufficient feed. It is more difficult to increase the flow of milk after a shrinkage from lack of full feed than to keep up a high activity of the secretion by artificial feed. When the habit of diminished milk secretion at a particular time of year is established, as it will be by repetition, it is not always easy to prevent it entirely by liberal feeding. The habit will also be transmitted to the offspring as a family characteristic that will diminish the value of the animal as a producer of milk. Give the cows extra feed so soon as the pasture begins to get short.

**Horses** need good care in these hot days of mid-summer. They should be kept clean by frequent currying and occasional washing of the legs and feet. The flies will cause the most inconvenience, and while working in the field some protection from them in the shape of nets or thin blankets (sheets) is a great comfort to the animals. Keep the stables clean that they may not harbor the flies or develop any bad odors. Horses that are at regular farm work need good food—better than grass alone will give. Oats or ground feed of some kind must supplement the pasture at night.

**Sheep** can care for themselves if they have a shady pasture supplied with good water. The matter of a ram to be used later in the season should be considered now and secured in time, if not already on hand. A full-blood will often improve the flock.

**Pigs.**—A run in a good clover stubble will be beneficial. The yards should be kept as clean as possible. A quantity of coppers sprinkled about the pens will deodorize and disinfect the place very satisfactorily and cheaply. Young pigs should be pushed now if they are for early market. A rapid growth secured now is of the greatest importance. If the stock is not what is desired begin to improve it at once by securing a pure-blood boar of some good breed to use in the herd.

**Poultry.**—Chickens hatched this month will, if well cared for, be large enough to get through the winter safely. It is not best to set any hens after July. Vermin breed very fast in hot weather and great cleanliness is necessary.

**Growing Seed Corn.**—It has been conclusively shown that any grain can be improved by a careful and continued selection of the seed. This is especially true of corn—and it is a grain in which a selection can be most easily and thoroughly ear-

ried out. Any farmer can select a given portion of his corn field for seed, and can thin, remove suckers, poor stalks—those with imperfect ears, etc., and in that way increase the growth of the best ears, with sound and vitally strong grain.

*Late Potatoes* will need constant watching for the Beetle, which should not be allowed to do any damage; kill the insects at their first appearance by an application of poison.

*Buckwheat* as a late crop to fill out with, when another has been removed or failed to grow, can be sown up to the middle of the month. A bushel of seed per acre is an abundance to sow.

*Cleanliness.*—The utmost neatness should be exercised about the premises in the hot weather. Garbage of every kind should be disposed of before it becomes decayed and is giving off a bad odor.

A *Compost Heap* is the proper place for all decomposable waste material. It should be situated in an out-of-the-way place, but near at hand, so that all weeds, waste, and decomposable litter of all sorts, may be carted upon it quickly and easily.

### Notes on Orchard and Garden Work.

The cultivator, whether of the orchard or garden, should make it a part of his programme to take a vacation, and this from necessity must come in mid-summer. This can be devoted merely to recreation—a most excellent use to make of it—or it may be turned to good account in making visits to others engaged in the same pursuits. A grape grower, for example, can make no better investment of his time and money than to go to Hammondsport or some other town on Lake Keuka, and from there visit the many neighboring vineyards. The nurseryman should go to Rochester or Geneva, N. Y., where he will find the largest nurseries in the country. Other cultivators can readily find centers where special attention is given to the things in which they are interested, and a visit to these will not only afford recreation, but will be very sure to pay in the instruction that an intelligent observer can always gain from seeing the operations of others.

Another matter should receive early attention—preparation for the autumn fairs. The fair season will begin in a little over two months, and it is none too early to consider the matter. The local fair, whether county or other, should receive the attention of every cultivator, whether he belongs to the class called “amateur,” or to the “professionals,” as those who cultivate plants of any kind as a business are called. A lively competition for the prizes, no matter how small these in themselves may be, is the only way in which a fair, large or small, can be made useful to the community. Every cultivator should make it a point to show his best products, and if any one exhibits better ones than his own he may be sure that there is something about varieties, or their cultivation, that he should learn. Besides these smaller fairs, those engaged in any branch of horticulture as a business, should show their products at the State or other large Fair, if only for the sake of making himself and his business known. It is none too soon to decide what shall be exhibited at the coming fairs, and what prizes upon the schedule are to be competed for, and to give the articles early attention in order that the exhibit may be a creditable one. If one competes for varieties of pears, as an example, for the half dozen or dozen to make the “plate,” should be selected before hand, and all smaller and poorer fruit near them on the tree be removed in order to secure the greatest possible development of those selected. So with other fruits, and a like course is to be pursued with vegetables, flowers, etc.

### Orchard and Nursery.

*Budding.*—So soon as the bark of the stock will “run,” that is, when it raises readily, and the buds are well formed, the budding may be done. In August, 1877, we gave full directions with illustrations, and as we can not repeat every year, the reader who is in need of such instructions is referred to the number mentioned, which if not at hand, can be sent by us, post-paid for 15 cents.

*Thinning.*—It will pay to thin the fruit from over-

loaded trees, even though it is getting late. The fruit that remains will be of better size and quality, and the benefit to the tree, especially if it is young, will make it pay for the labor of thinning.

*Grafts* will need to be looked to; they must not be interfered with by surrounding branches, some of which may need to be cut away. All grafts growing too vigorously should be pinched back.

*Pruning* can be done during this month. An open head to the tree should be kept in mind, that the air and sunlight may readily reach the interior.

*Marketing.*—The early fruit will be largely marketed this month. Too much care can not be exercised in having it put up with neatness. Tidy packages neatly marked and filled with selected fruit, always bring a good price, even when the market is full of inferior fruit. Get and hold a reputation for uniformly good fruit—as it pays.

*Tent Caterpillar.*—The nests that have escaped the earlier rounds should be destroyed, or these greedy “worms” will rapidly strip the trees of their leaves, and thus greatly retard their growth.

*Codling Moth* is best caught by using bands of hay or paper put around the trunks of the trees. Remove the bands every week or so, and kill the insects that have gathered beneath them.

*Blight* is the most mysterious of all the enemies which affect the success of the fruit grower. Other troubles either give warning of their approach, or are to be traced to some direct cause. With this, the fruit grower's only knowledge of it is the death of a part of the tree, and not rarely the whole of it. The tree that was yesterday a model of thrift and productiveness, will be to-day a mass of dead wood, bearing scorched and blackened foliage, a cucumber of the ground. When it appears, cut away the portions killed, removing the whole tree if found necessary.

### The Fruit Garden.

*Grape-Vines.*—For the first two years a stake is a sufficient support, after which some kind of trellis should be provided. Keep the shoots you wish to preserve well tied up, and as others start remove them. The little branches that are coming out at the point where the leaf joins the main stem, are the *lateral*s, which should be pinched back to the first leaf, and if it makes another start, pinch it back again. Stop any shoots by pinching when they are as long as desired. The insects that appear are in most cases best removed by hand-picking.—See article on this subject on page 273.

*Mildew* appears first in white patches on the under surface of the leaves, and afterwards upon the fruit, and should be kept in check by using the Flowers of Sulphur, applied with a bellows on a still morning. It is best to apply the Sulphur when there is dew upon the vines, or just after a rain, as the dry powder sticks to the vines better. The sulphuring should be repeated at intervals of a few days until the mildew disappears. Bellows for the purpose are sold at the seed and implement stores.

*Currants.*—If the fruit is for making jelly, pick it when well colored and before it is dead ripe, but if to be eaten fresh at home, it should remain on until thoroughly mature. The long shoots that push up from the interior of the bush should be broken off while young. Any other thinning that is necessary may be done now with advantage.

*Blackberries and Raspberries.*—Those canes that are to be left for fruit bearing next year should be stopped by pinching at 6 feet for Blackberries, and 4 feet for Raspberries. All other shoots are to be treated as weeds and cut away early in their growth. So soon as the fruit is off the old canes have finished their work, and should be cut away.

*Strauberrries.*—When the picking is over, remove the mulch of straw, etc., give the soil a good coat of manure, well forked in, and keep the bed clean of weeds. If the single row system is followed, the runners are to be kept cut off, unless plants are wanted to set new beds. In the alternate system the runners are to be encouraged to make plants in the forked and manured “paths” between the old rows. Pot layering is now quite extensively practised, and is to be commended for private gardens. It consists in sinking small pots filled

with rich soil in the soil of the bed into which the runners may strike their plants; afterwards plant, soil and all is transferred to the new bed. Plants thus obtained will bear a good crop the next season.

### Kitchen and Market Garden.

We made special mention of the value of the hoe and rake in the garden last month, and it can not be too forcibly stated that upon their frequent use the success of the vegetable garden depends; at this time, when the planting is pretty well over, the tending of the growing crops is the principal work.

*Asparagus.*—Let the plants grow up and form a dense mass of green. Pull out any large weeds—the shade will prevent the growth of small ones.

*Beans.*—Bush sorts, like the “Refugee,” may be still planted for late use and pickling. The Limas, if very vigorous, and inclined to run beyond their poles, may be pinched at the top of the pole.

*Beets.*—Sow for a succession for greens and young roots. Keep the weeds out and the soil loose.

*Cabbage and Cauliflowers.*—Set for late crop in a rich soil, and watch for the worms, which, if they appear, may be killed by the use of hot water.

*Celery* should be set now, in rows three feet apart and six inches in the row. The trench system is entirely superseded by that of cultivating on the level surface and blanching late in the season by throwing up the earth in ridges around the plants.

*Carrots.*—Hoe so long as the tops do not interfere with the work, and thin when too close.

*Corn.*—Early sorts may be planted for late use and drying. The seed of the best specimens should be saved for planting next year.

*Cucumbers.*—Dust with ashes to keep off the “bugs” and other insects. Pick the small fruit every day for pickles. Those two inches long are best.

*Egg Plants.*—By using liquid manure, the plants may be forced greatly. The fruit should be kept off of the ground, by using a layer of straw.

*Melons.*—The late set fruit will not ripen, and had best be removed. Save seed from best specimens.

*Onions.*—When the tops lie down, the onions are ready to be harvested. Store in a cool airy place after being thoroughly dried in the sun.

*Sweet Potatoes.*—The vines should not become rooted at the joints. Move them when hoeing.

*Squashes,* unlike the sweet potatoes, may strike root at the joints with advantage. Keep the bugs off.

*Tomatoes.*—Use some sort of trellis to keep the fruit from the ground; if there is no trellis, use brush or even hay to keep the fruit from the ground.

### Flower Garden and Lawn.

The main work now is to keep everything in order.

*Lawn.*—The mower must be frequently used, and the corners, borders, and out-of-the-way places “trimmed up” with a sickle. Any large weeds that come up, should be dug out by the roots.

*Walks and Drives* will need an occasional hoeing and raking, and the roller passed over to smooth and harden them. The margins should be neatly trimmed with large shears at frequent intervals.

*Bedding Plants* need much care, as they grow rapidly, and unless the knife is frequently used, will get in bad shape, and attractiveness is lost.

*Dahlias, Gladioluses, etc.,* will need stakes to support them, but simple unnoticeable poles firmly driven into the soil are preferable to painted sticks.

*Climbers* are to be looked to, and care taken that they have ample means of support.

*Annuals and Perennials,* should have no weeds amongst them. Unless seeds are to be saved, cut away the clusters as soon as the bloom fades.

### Greenhouse and Window Plants.

This is the most difficult time of the year to make the greenhouse look attractive. The beauty and attraction are now out-of-doors. Much shading must be done, with either heavy coats of white-wash on the glass, or by using muslin. Frequent watering and wetting down of the walks, etc., is necessary to keep the house cool. Fumigate at frequent intervals. Get stock of moss from bogs if the weather is dry, and soil from the woods.

## Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending June 10th, 1880, and for the corresponding period last year:

## 1. TRANSACTIONS AT THE NEW YORK MARKETS.

**RECEIPTS.** Flour, Wheat, Corn, Rye, Barley, Oats.

Cucumbers, per 100.	75 @ 1 50	— @ 2 50
Lettuces, per bbl.	— @ 1 75	1 50 @ 2 75

Increasing ease in money has contributed to activity at the Stock Exchange, where values—though variable—have been generally on the advance; and served also to stimulate dealings in Real Estate at improving prices.... As usual at this season of the year, general merchandise has been comparatively dull, the demand narrowing down to the most urgent requirements of buyers, who have been enabled in several instances to obtain concessions, under a more or less decided pressure to place supplies.... Cotton has diminished perceptibly in the inter-

est shown by operators, whether for prompt or forward delivery; and has hardened slightly in price, as the offerings have not been very urgent.... Wool has also been in light request and has further declined, leaving off irregularly, pending the free receipt of the new clip.... Naval Stores and Petroleum have been advanced, partly through speculative dealings, and have shown more animation.... Provisions have been moderately active, but have been quoted, in nearly all instances, lower. Offerings of Butter have been on a liberal scale. Cheese has recently met with more attention, in good part from shippers, and closed with some indications of firmness on the more desirable makes. Eggs have been on the advance within the past few days, on a better demand.... Breadstuffs have shown decided activity—largely on speculative account, which has been accompanied by more or less serious disturbance of values. Wheat felt the influence of speculative manipulation, most notably No. 2 Red, of the Winter grades, having been the favorite, was run up very rapidly against operators having deliveries to make on May contracts—touching, at one time, as high figures as \$1.46½@1.47; but, following the May settlements, broke down to \$1.30@1.32, and left off at about \$1.30@1.31, with corresponding depression and disturbance in options,—especially for June,—which month is now the center of the speculative interest. Increasing receipts, rather unfavorable foreign market advices, and generally encouraging crop reports worked, near the close, against operators for another advance. Corn ruled higher through the earlier dealings, but has weakened materially within a few days, as the supplies have been gaining on the requirements of buyers. Oats have also fluctuated widely,—leaving off much lower, on freer and urgent offerings. Rye has been in light stock and wanted for export at much higher figures. Flour has been generally on the decline, on a moderate movement for home use and shipment. The visible supplies of Wheat—embracing the hoards at lake ports, in transit, and on the seaboard—at latest dates, embraced about 20,395,000 bushels,—of Corn, 15,785,000 bushels; of Rye, 365,600 bushels; of Barley, 487,000 bushels, and of Oats, 2,731,000 bushels, against on January 31, an aggregate of 30,100,000 bushels Wheat, 13,100,000 bushels Corn, 979,000 bushels Rye, 4,155,000 bushels Barley, and 3,080,000 bushels Oats. Ocean Grain freights have been unusually active—largely in the speculative line—but at lower rates, closing rather stronger, including by steam to Liverpool, 3½¢@4d. per bushel; to Bristol, by steam, to 7d. per bushel; to Antwerp, by steam, to 8½¢d. per bushel, and by rail to Cork, for orders for vessels of average carrying capacity—say 3,000 to 4,000 qrs.—is 3d. @ 6d. per qr. of 480 lbs.

## Prices for beefs the past four weeks were as follows:

WEEK ENDING	Range.	Larger Sales.	Aver.
May 17.....	8 @ 10½¢.	8½ @ 9½¢.	9½¢.
May 24.....	8½ @ 10½¢.	8½ @ 9½¢.	9½¢.
May 31.....	8 @ 10½¢.	8½ @ 9½¢.	9½¢.
June 7.....	8½ @ 10½¢.	8½ @ 9½¢.	9½¢.

**Beefes.**—The receipts for the first week were very heavy, with a large call for export, and a good demand for home use. The market has been unusually steady throughout the month, and it will be seen from the table of averages that there has been but little rise and fall in this market. The decline in the third week was caused by the extreme heat, which made the market dull, but with a quick recovery—and at date of writing both exporters and home traders are operating freely with an active market. Colorado corn-fed cattle sold at 8½¢@9c. Choice native steers, to dress 56 lbs., brought 8½¢@10c., and a few selected to dress 57 lbs., sold at 10½¢@10c....

**Milk Cows.**—There has been a great falling off in the number of cows sold; the average not being much above one-half that of last month. The very light arrivals have been sold at prices ranging from 35¢ to 50¢....

**Calves.**—A very liberal supply and the warm weather caused a slow market in the middle of the month. Buttermilk calves were dull and not wanted except at low figures. Prime Veals were in some demand; mixed lots of the former sold at 3½¢@4c. and select Veals at 4½¢@5c. with a few exceptionally fine at 6c....

**Lambs.**—The receipts at the first of the month were large, and the market was under the control of the buyers. Lambs were abundant and dull at first, but the demand increased through the month, until the last week, when they were again abundant and at low figures. Colorado 3½¢@4c. for choice wethers....

**Hogs.**—There has been a considerable falling off in the receipts of hogs. Market quoted nominally at 4½¢@5c. at the close of the month; none for sale alive.

**The Horse Market.**—There is a moderate busi-

ness in horses though the spring trade is over. Dealers are confident that selling rates will have to be lower for common stock. A few fine animals are coming in from abroad—among them is a fine Norman Stallion from France to go to Ohio. Street-car horses sold for \$110@ \$130, and good work horses at \$150@200. Good carriage teams, according to speed, etc., ranged from \$450 to \$800.

**Potash Salts.**—"H. L. B." Erie Co., Pa. The articles on "Science Applied to Farming" in the *American Agriculturist* for November and December, 1877, and April, 1880, give full information about the German Potash Salts. It is impossible to lay down rules for their use to apply to all cases. The only way is to "try and see." They both succeed and fail on all sorts of soils, from gravel to heavy clay. For potatoes they are generally profitable. For clover, corn, and grass they do well as often as they fail. For wheat, oats, etc., they are less commonly profitable. Such is the testimony of our field experiments and of general experience. For general use, the muriate, with 80 per cent or more of chloride of potassium, corresponding to 50 per cent or over, actual potash, and sold at \$40.00 to \$45.00 per ton, is the best grade to buy, because it furnishes more potash for the money than any other. For tobacco and potatoes the sulphates are recommended on the ground that they have a better effect upon the quality of the crop. But they are harder to obtain pure, are more costly, and, so far as the testimony of our experimenters goes, the muriate brings potatoes of excellent quality. The Leopoldshall Kainit is a low grade potash salt, averaging about 12½ per cent actual potash, and consisting largely of common salt. It is not to be recommended unless it can be had at very low rates; it is not worth more than \$13.00-\$16.00 per ton.

**Hen-Manure.**—"S. C." Lynn, Mass. Hen-manure varies greatly in composition and value, according to the food of the fowls; whether they are growing or laying eggs or not; and especially how much it is decomposed; and how much water, earth, straw, etc., it contains. Three samples analyzed at the Connecticut Experiment Stations gave from 44 to 71 per cent of water, 0.8 to 0.9 (8 to 9-tenths of one) per cent of nitrogen, 0.4 to 0.6 per cent phosphoric acid, and 0.4 to 0.5 per cent potash. That is, they had about one-tenth as much of the most valuable fertilizing ingredients as No. 1 Peruvian Guano. The samples had about as much phosphoric acid and potash, and twice as much nitrogen, as ordinary horse or cow-manure. At valuations current for commercial fertilizers they would be worth about \$5.00 per ton. The water and earthy matters amounted in each of the three samples to a little over four-fifths of the whole. The pure dry dung would contain some 4 per cent of nitrogen, 2 per cent each of phosphoric acid and potash. The reasons why the pure dung is so inferior to guano, which is notably bird dung, and contains (No. 1 Standard) over twice as much nitrogen, and six or seven times as much phosphoric acid, are mainly, that the guano birds live on fish, a far richer food than that of hens, and that the hen-manure is moist and apt to lose considerable nitrogen by decomposition (fermentation, "heating," etc.)

**Profitable Farming.**—In the conclusion of a long letter to an exchange, Dr. J. B. Lawes remarks; "Although the process and conditions of growing wheat in England, and corn in Maryland, differ in certain respects, still it is my opinion that in both countries, the largest crops will be found to be by no means the most profitable." Beyond a certain point of high culture farming becomes of the "fancy" sort, but in general, our's is not of that sort, and for good reasons will not be, for some time to come: The West is large and still fertile.

## Interesting Announcement

FOR ALL YE BOYS,

From 5 to 105 Years Old!

Scroll or Fret Sawing is one of the most delightful amusements, combining pleasure, utility, and a development of taste and skill. Every home, however humble or magnificent, is more beautiful if adorned with brackets and other work produced by home hands. Hundreds of thousands of such homes now exist, where only the slow and tedious hand-frame fret saws have been available. More recently the foot pedal and multiplying wheels have come into use, and the increasing demand has tended to cheapness and improvement. We are now happy to announce another LARGE ADVANCE in

### Perfection, Cheapness, and Portability,

by which is secured stronger, better working machines; a material reduction in price, and a great saving in cost of carriage or delivery, as well as in storage room when not in use, with sundry other improvements and advantages.—All the above are secured in

### Beach's New Folding Fret Saw.

Figure 1 shows it ready for use, while in half a minute or less it can be folded (without removing the saw) to the form, figure 2, occupying but a quarter of the space, to be set away, or put in a small box for sending anywhere at small cost for carriage. By a simple arrangement the table is lowered to a convenient working height for a boy of 5 or 6, or raised high enough for the tallest man, and at every height it stands firmly.

It has a tilting table, and will execute very fine scroll-work or inlaid-work. The clamps will firmly hold any saw, from the finest No. 00000, up to No. 10; they are readily and quickly inserted or changed. A space of 20 inches behind the saw allows quite as large pieces to be worked as any other instrument of the kind in the market.

By an ingenious arrangement, there are no dead centers, but the wheel starts right off the moment

securing great durability, while the frame, of tough white ash, or other tough timber, is formed to secure the greatest strength. The whole is so simple that A CHILD CAN WORK IT. Parents will appreciate the convenience of such an instrument, of full size, yet quickly folding up so as to be set in the corner of a closet if desired. Though as strong and durable as any one could desire,

**The Weight is only 15 lbs.**

With all the above advantages, and its great superiority over any other hitherto produced,

**The Price is only \$2.25,**

which includes full instructions, so that a beginner can go to work at once. It is packed in a neat box and is delivered to any express office in New York City FREE. The small space required, and the lightness, will reduce the cost of carriage very greatly, as compared with other machines for similar work.

The Editors and Publishers of the *American Agriculturist* were so pleased with this new machine that they at once secured the control of it for the benefit of their readers, though it will be supplied to others as soon as it can be produced in sufficient quantity. It will be forwarded by express or otherwise, as directed, in the order of calls for it, at \$2.25 each; or

Fig. 2.—THE SAW FOLDED.

### FREE as a Premium.

A special object in taking hold of this new machine was to secure it for our new Premium List now in course of preparation.

In the meantime, any one will be presented with one in return for four yearly subscriptions to the *American Agriculturist* at \$1.50, or for eight half-year subscriptions (July to December inclusive) at 75c. each. On receipt of address we will mail our full instructions for using this charming Scroll Saw.

### Some Things this Number Contains.

Numerous helpful hints about the Work of the Month, will aid many in this busy season; see pages 254 to 256.

One of the special features of this number is the Second Prize Essay on KEEPING ONE Cow, which should be read by every subscriber; pages 270-271.

Plans and specifications for a Country and Village House, costing \$3,500, will meet the actual wants of many who desire to build a neat and commodious dwelling. Page 264, with numerous illustrations.

Further experience on the subject of Fences and Fencing, is given on page 261.

Prof. Atwater gives a thorough treatment of the subject of Hungarian Grass, on page 261.

The Humbugs are sundry and important; pages 258-259.

An interesting and instructive article may be found on Training Animals on page 269.

A very practical Plan for Planting Fruit Trees, by S. B. Parsons, with diagram, may be seen on page 273.

For a variety of Household information, including Faith Rochester's entertaining and instructive Notes, see pages 276-277.

The Boys and Girls will know where to turn for their Special Department, and will not be disappointed; pages 278 to 280.

The Basket is unusually full of short items, on various important subjects, pages 257-260, 286-290.

The Army Worm, so destructive to farm crops, receives the full attention it deserves, page 260 and 262.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**To Subscribers to "Land and Home."**—Special Notice.—The subscribers to "Land and Home" will receive the *American Agriculturist* for the remainder of the time for which they have paid their subscriptions to that journal. Those who have already paid in advance for the *American Agriculturist* will have their time extended for an equivalent period. In other words, whatever may have been due in subscriptions to that journal when it discontinued, will be made good by supplying the *American Agriculturist* at the current rates.

**Where to Get Things Wanted.**—Many thousands of letters come to the Editors every year (some with and some without "return postage"), asking where they can obtain from trustworthy parties, implements, animals, poultry, seeds, plants, fertilizers, and a great variety of other things, all of which questions we try to answer when we can. But nine out of ten of these letters, and much valuable time of both writers and respondents, would be saved, if the inquirers would take the little trouble required to just look through the advertising columns, where usually, in one number or another, several parties announce the very things asked about. We try to keep out all parties not trustworthy. If any mistake occurs, after all possible care, we can only acknowledge to having been deceived, for we do not admit any advertisers whom we would not ourselves patronize when wanting the things they offer. (The Editors have the "veto power" over any and every advertisement proposed for these columns.) It will always pay to read through the business columns to see what is offered and by whom, and useful hints are often derived from reading what others say and how they say it. New ideas are thus started up in one's mind.—When corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**SEE:**—All interested in the hidden truths and beauties of nature should see them, and this can be done by the aid of a good Microscope. See a full account of the *American Agriculturist* Compound Microscope, page 286.

**To Get Rid of Chicken Lice.**—Vermin is the pest of poultry, and when chicken houses get thoroughly infested, it is not an easy matter to cleanse them. If the house is washed with a hot lime wash, and the roosts are rubbed with a mixture of kerosene oil and lard, the lice will be made uncomfortable, and if this treatment is repeated a few times, the house and also the fowls will be quite free from vermin. If the house is, as all poultry-houses should be, detached from barns and other buildings, it may be fumigated. Shut it up tight and close every opening. Then place a pan of live coals on the ground (or if it must be on a wooden floor, put down a few shovelfuls of earth, or coal ashes, to hold the pan). Throw on a handful of lumps of brimstone, and get out quickly, closing the door tightly. If the work has been thorough, no lice can be found at the end of a few hours. The white-washing, etc., may be then done.

**Stumps.**—It is not wise to employ any expensive methods of getting out the stumps on a new piece of land, that is not from location, or otherwise of very great value. It is in most cases cheaper to let stumps rot out. There is a general desire to clear and clean a piece of land all at once, but as in many other things, it may be, "the more haste, and the less speed." The use of dynamite, or any other quick acting and expensive method, is recommended only when the room the stump occupies, is worth a considerable more than the trouble and expense of taking it out while green and difficult to remove.

**Insure Farm Buildings.**—The average farmer, when his barns are full of grain and hay, can be almost ruined by a fire unless he is well insured; and it is at just that time that barns are most frequently destroyed by fire. Lightning comes mostly in the summer months, and is a common cause of barn fires. It is best to be insured in a good company near at home.

**The House Plan.**—For several months we have been giving our readers plans and estimates of cottages or houses of moderate cost, and suitable for only a small family. This month a larger, more commodious dwelling is presented in all its details, and will doubtless answer the ends of many, who contemplate building a house that will cost in the neighborhood of \$3,500.

Fig. 1.—BEACH'S FRET SAW READY FOR USE.

the foot presses the pedal, while it can be instantly stopped by simply pressing the knee against a brake. The upper clamp is hinged to be thrown up for changing the saw, or for inside work. The working parts are iron or steel, finely fitted,

**Two Acres—What can be done on them.**—There are books on "Ten Acres Enough," "Five Acres too Much," "My Farm of Four Acres," etc., all interesting and instructive to many people; but for a short, concentrated, telling account of what has been done, is being done, and can be done on "Two Acres," we commend the reader to go through with the Essay on "Keeping One Cow," on page 270 of this paper.—There is hardly a cultivator in all the country, whether of a large or small farm, or of the smallest village plot, that may not get some useful hints from Mr. Battles' plain account of his method and the results.

**The Dog for the Farm.**—If a farmer stands in need of a dog, he should have a good one. The farm dog to be a profitable adjunct of the farm should have duties to perform, and should possess certain valuable qualities that will enable him to do his duties well. He should be a faithful watcher of persons and property, and at the same time of a kind disposition. He should be gentle to the live-stock of the farm, and above all, obedient to his master. A good farm dog is a very knowing one.

**Pig Labor.**—Some one has recommended the pig, as just the creature to work upon the compost heap, and keep it thoroughly stirred up by frequent rooting for stray ears of corn, that are purposely placed in the heap. Swine only pay on the farm, when all their efforts are bent, first towards making a frame, and next to the laying on of fat, and anything that leads them away from this work, is a source of loss. The pig as a farm laborer, to be used for turning the compost heap, is a failure, and the farmer who goes on the principle that pigs may be made "beasts of burden" in the sense of getting profitable work out of them, is, to say the least, not on the right track.

**Poll Evil.**—This trouble is an abscess at the back of the head where it joins the neck, and is not serious unless it reaches the bones or joints of the neck. The remedy consists in opening the abscess, to allow the accumulated pus to escape, after which the cavity is dressed with a solution of half a dram of Chloride of Zinc, to a quart of water. If the neck becomes stiff before any remedy is applied, the animal is in many cases beyond help.

**Summer Day Comforts.**—Many of our readers have promptly availed themselves of our proposal, in the June number, to furnish substantial "Hammocks,"—now so popular as summer day comforts,—at a moderate price. We make, of these articles, a special offer for July, which will interest our subscribers and others, and will be found on the last cover page.

**Paper Barrels.**—Machines capable of making 200 paper barrels daily are now in operation. Strange as it may seem, barrels for sugar, kerosene oil, lard, and even gun powder, are now made out of a paper pulp.

**Stones in the Meadow.**—As the knives in the mowing machine strike against the loose stones in the meadow, or become broken by the small ones that get between the guards, they are not pleasant reminders that these obstructions should be removed from the surface of the meadow. There is no better time for doing this, than just after the grass crop has been taken off, while the surface is comparatively bare, and the stones often loosened by the horse rake, and other haying implements. A few hours now spent in gathering up the loose surface stones, will be well spent, and may prevent a serious break to the mowing machine, and that in a hurried time of work.

**"A Vine."**—"W. S. H." The specimen was nothing but fragments when it reached us; when the plant flowers send again. While sometimes we can guess from the leaves only, we never feel sure unless we have the flowers; the fruit is often necessary for determination.

**Success with Small Fruits,** by Edward P. Roe, New York: Dodd, Mead and Company. This book is phenomenal in every respect. The art of our best artists, and the highest skill of the wood engraver are here made to illustrate such prosaic subjects as grubbing a stony field or to make beautiful and attractive the most stupid and monotonous work of berry picking. The author brings the graces of a style that have given him a place among the popular writers of the day, to tell how berries are grown, picked, and marketed, and quotations from books upon his business desk are more frequent than are those from the books of his library. A large share of the work appeared as a series of articles in "Scribner's Monthly." These are brought together, copiously augmented by other matter, and form a sumptuous volume of over 300 ample pages. The engravings may be regarded as of two kinds, fruits and fruit-growing scenes. In representing the fruits, while a great amount of skill is shown in presenting them artistically, any tendency to exaggeration has been wisely repressed, and they show the varieties at their best without sacrifice of their accuracy as pomological portraits. These

are the most important engravings, the others being mere embellishments—and beautiful ones they are. Both the humorous and the sentimental aspects and suggestions of fruit culture have afforded themes to such artists as Homer, Gibson, Sheppard, Mrs. Foote, and others. As to the text of such a work, the author can hardly hope to give much that is new. Its great value consists in its foundation of hard facts. If the facts are not sure, no graces of literature, or charm of illustration can make the book of any value. The title of the work, "Success with Small Fruits" indicates its scope. The author has been successful; he tells the methods which led to that success, and gives instructions that may be safely followed, and gives them in an attractive form, as he well understands the art of "putting things." Not the least interesting portion of the work, and that which has the best claim to novelty, is the description of strawberry culture in the Southern States, and it has also afforded themes for some of the most pleasing pictures. In a work of this kind the author's most difficult task is to give his estimate of the relative value of varieties; he is sure to invite discussion if not make some enemies. If he is a dealer in plants, he is placed in a delicate position, as there are those who are ready to attribute even moderate praise of a variety to a desire to make sales. Fortunately for this author, he has already established a reputation for fairness in this respect, and has been quite as ready to point out the faults of his own seedlings as those of others, and in the present work he has given the opinions of others as well as his own. We may sum up our opinion of this work in two words—Beautiful and Useful. Sent by mail from this office at the publishers' price, \$5.00.

### Sundry Humbugs.

For once we are disappointed—we were about to write agreeably disappointed, but refrain out of deference to those who hold that the term expresses an impossible condition, and that whoever claims that disappointment can under any conditions be agreeable, commits a solecism. Nevertheless, we are disappointed that things did not turn out as we expected they would, and are glad that they did not. With the general revival of business that set in when specie

payment became an assured fact, we expected that the large class who get their living by their wits would experience a renewed activity; that the old trade of getting something for nothing would start with new life, and that fraud and swindling would present themselves in new disguises to all the more readily ply their calling. But while honest trade and labor are prosperous, humbugs do not "hoom" at all. In all these past years of dullness, in no year, including that of "the panic," has there been such a lack of activity, such an utter dearth of novelty, than

#### THE LAST FISCAL YEAR—

beginning with July last—has shown, and the last quarter of that year has been marked by a dullness that is almost painful in its intensity. We doubt if in the past 15 years there has been a trimester (as they say at Cornell University) that did not produce some entirely new swindling scheme, or at least an old one so rehabilitated that it was as good as new, except this last. Are we to infer from this that the world is growing better? We wish we could. But we fear that it is only the hush that precedes the outburst of the storm. It must not be inferred from what we have said that no swindling is going on, and that money no longer passes from the pockets of the credulous to those of the sharper who gives no equivalent in return. We refer only to the utter absence of new tricks. Perhaps the most marked feature of the humbug market just at this time is a partial revival of one of the oldest of frauds. The offenders of

#### THE QUEER, OR COUNTERFEIT MONEY,

were, just after the war, more numerous than any other class of swindlers. In our humbug column of those days it was not rare to give the names of a dozen or more chaps or firms claiming to have had money which they wished to sell for good. The game flourished for a time, but it was so thoroughly exposed in all parts of the country that it dwindled and finally quite died out. There was a period of a year or two in which we heard nothing of it; then it gradually resuscitated, and of late it has regained some measure of its old-time activity. Indeed, in a budget of letters relating to humbugs, which, considering the season, is quite large, about half relate to this fraud. As this old affair is new to many of our readers, we describe it in brief. If we had a collection of the

various circulars that have been sent out in the prosecution of this swindle through all these years, it would be as great a curiosity in the literature, as is

**THE ROGUES GALLERY IN THE PORTRAITURE,** of rascality. One of Dickens' characters, Miss Moucher, had a great variety of names for the ronge and other beautifiers she sold to her lady patrons, but the vocabulary of counterfeit money is much larger. Just now the favorite name is "Cigars." The cigar circular is too long to copy in full, but we give sufficient of it to show its style and drift:

"Dear Sir:—My traveling agent, who passed through your section recently, informed me that you were a man of a speculative disposition like myself, and that you were willing to make money rapidly, provided it could be done safely. To come to the point at once, I am a manufacturer of **Cigars** made of Green Tobacco. I am the only person who has been engaged in this business in this vicinity for years. I am not only an expert in the business myself, but I employ none but the best talent in the country to assist me. Everything in connection with my business is as well organized and as well conducted as any business in the land. My **Cigars** though not genuine, are as difficult to detect as anything can be. I presume that you understand me. I do not ask you to send money in advance, nor will I send my goods on credit, as I can sell all I wish to persons for cash. \* \* \* I desire you to come on to the city and examine my stock at your leisure. \* \* \* My prices are as follows:—For \$150 I will allow you \$1,200; for \$250 I will allow you \$3,500; for \$350 I will allow you \$5,500. The sizes of my **Cigars** are Nos. 1, 2, 5 and 10. You will understand I am willing to allow you \$300 in goods for your railroad expenses. You are at liberty to bring a friend with you if he has money. But bring a man who can keep a still tongue. If you make up your mind to come, notify me at what hotel you may stop here. If you are not familiar with the name of a suitable hotel here, write to me and I will furnish you all the information you desire. \* \* \* Do not bother me about small orders or samples which are usually sent by mail. An inquisitive postmaster, or some one who is in the habit of getting your mail for you, may be tempted to open your letters. In case you intend coming on immediately notify me three or four days in advance of your starting, so that I can be prepared for you. Read the printed slip inside very carefully. Remember that this circular is sent to very few. \* \* \* It is printed in my private office."

The "printed slip" referred to is a new dodge. The slip, apparently cut from some paper, gives an account of the arrest of a man who had \$3,000 in new money in his valise, on suspicion of being a counterfeiter. But the "Cashier of the Third National Bank was sent for, who, after a critical examination of the bills, pronounced them to be genuine"—and the man was discharged. A very neat way that, of showing how excellent was this batch of "cigars." But all do not beat around the bush and have other names;

#### THEY OFFER COUNTERFEIT MONEY

in their circulars, which set forth its great excellence, and coolly inform the one who receives the document that he has already taken and passed some of the very same bills without knowing it. These circulars, in all their different forms, have a few features in common. They all present the chances of making money rapidly and without risk, in a taking manner. All claim that the senders will act in the most honorable and upright manner, and all warn the one who receives them that the business can not be done through the mails, but only in a personal interview. We can imagine the indignation which our readers, especially those who have not known of the matter, must feel at receiving such a circular, which contains nothing less than a proposition to

#### BECOME A COUNTERFEITER'S ACCOMPLICE.

It is quite natural that an honest person should feel that he is doing wrong, knowing what he does (or what he thinks he does) in not doing something to bring the rascally maker of the proposal to justice. Some of the letters we receive are quite amusing. The writer usually suggests that we hand the matter to the police authorities, but sometimes one will propose a regular plan for the capture of the counterfeiter and his money, and offers to come to the city for the purpose of putting it into execution. The matter seems to be beyond the reach of the law. If one of the chaps could be detected in selling his "Cigars" or counterfeit money, he could be easily brought up, but in the whole affair, notwithstanding the minute description in the circulars, there is

#### NO COUNTERFEIT MONEY IN THE OASE.

Among the thousands of such circulars sent monthly to all parts of the country, now and then one will fall into the hands of a person who is ready to make money dishonestly if he can do it without detection, or one of obtuse moral sense who does not consider anything wrong that pays. The sharper arranges the preliminaries with a person, who is to go to a designated third-class hotel and engage a room; he is to have his \$100 of good money ready and to receive \$1,000 of "Cigars" in exchange. It all works well—buyer pays his good money, and gets his counterfeit in a neat packet. Eager to see his new purchase, he is about to open his parcel, when he is stopped by the other, who tells him that as he came into the hotel below he "saw that there were a couple of detectives on the look-out; I heard some talk about counterfeiters, and I would advise you, with all that counterfeit money in your possession, to be a little careful; I would advise

yon to get out as soon as possible, and as our business is done, I'll bid you good evening"—and goes. It is very likely that the thoroughly frightened victim will start for home at once. Sometimes the sharper is so polite that he will see the other safely to the ferry-boat or train. Sooner or later the purchaser inspects his counterfeit money. He finds upon opening it that he has

A PACKET OF NEATLY CUT NEWSPAPERS, and his good money gone beyond recovery. Enough of transactions of this kind become known, to show that they are of more frequent occurrence than one would suppose. Sometimes a victim is foolish enough to complain to the authorities, but if the victim is a person of any shrewdness he will see that to complain is to expose the fact that he was willing to become a "shower of the queer," which is rogne's slang for passing counterfeit money. This is one of those frauds that can injure no honest person. No one can become its victim without first acknowledging that he is willing to defraud others, and such can get no sympathy from any one....

THE FARMER WHO SIGNED HIS NAME, this time hails from Pennsylvania. Heretofore he has lived mostly in New England and New York, with a few of him in Michigan and the West; but we do not think we have heard of him in Pennsylvania before. But it is the same old story, only it is not mowing machine sharpeners, or other machinery, but this time it is a Fertilizer. "Two well dressed men of pleasing address, drove up to the house of Mr. Samuel Brown."—These are always in couples, always well dressed, and have pleasing address, and always "drive up" somewhere—how many times have we read it! The "Well-Dressed" represent the Company that makes the Fertilizer. Only a few selected agents are to be appointed in each county. Nothing to pay until the stuff is sold. The "Well-Dressed" had inquired among other farmers, and learned that Mr. B. was the proper man to be appointed as agent—Mr. B. thought so too—so it was agreed. The "W. D." would report to the "Company," and the Fertilizer would be sent.—"As a mere matter of form you know,"—the W. D. had to send in a statement, to show that they had appointed a substantial agent, so out come pen and paper. "How much land have you Mr. B?—and what is it valued at?—Horses?—Cattle?" etc., etc.—"and not encumbered by any mortgage?"—"Oh no."—There, please look that over Mr. Brown, all correct isn't it?—Please put your name to it as a memorandum—mere matter of form you know."

#### BROWN GOES AND DOES IT.

The "W. D." go—days and weeks go—Fertilizer don't come, but a note does. It was left for collection—in a distant city, but to oblige Brown, it might be paid at the bank in the village near by. \$198.83 is the amount. Brown declares he never signed a note for that amount, and won't pay it. We hope that he won't.... Last month it was silver plated ware, just now

#### IT IS A SOLID ROLLED GOLD RING,

about which inquiries are made. A party advertises to send for 25 3c. postage stamps, a "Heavy Plain Band Gold Ring," and several have sent us the advertisement, and asked if it does not belong in our Humbug Column. We do not see why. The advertisement offers to send a gold ring for 25 three cent stamps. We see nothing about the advertisement that makes us doubt that the stamps will bring 75 cents worth of Ring. If any one expects to get any more than 75 cents worth of Gold Ring, Red Herring, or Soft Soap for 75 cents, he has lived in this selfish world to little purpose, and is altogether too "child-like and bland," to endure the disappointments that the future has in store for him.... In the medical line, all other curative agents are overshadowed by the toys called Electric Batteries. Indeed, we are just now enduring what may be termed

#### A BOOM OF THE BATTERIES,

and the number increases; new batteries with new claims are offered. We can not say that the later comers claim to do any more than the first ones did, for those would cure everything, but these propose to do it in a different way. A few months ago we noticed a Boston Battery which was an improvement on the others, as it drove out disease, and then kept it out by means of a pad, which absorbed it. Now we have another Boston Battery far ahead of the other. This not only sends out disease, but

#### SENDS IN THE MEDICINE,

for do we not read of "Dr. Rhodes' Electric Transfusing Battery. The only Battery in existence capable of being charged with medicinal properties which can be transfused into the system." This, moreover, differs from other batteries in being worn on the spinal column instead of on the breast. In whatever respect these batteries may differ from one another, they all agree in one particular: each one claims that his is the only useful one, and that all others are of no account. The latest is

PROFESSOR CALDWELL'S MAGNETO GALVANIC, and the circular setting forth its merits is a remarkable document. There is a picture of a man without any bat-

tery, labelled "Before Using," and another picture of a man with a battery, and this is labelled "After Using." Now if these pictures are accurate representations of the man before and after, we protest against its use. One has only to wear one of these things, and his own mother would not know him. A rogue has hereafter no need to go to Canada to escape justice. All he has to do is to wear one of these batteries, and if these pictures are true, he becomes another man altogether. We have already told about Boyd's Battery and his claim that his electricity

#### "WAS FORMED IN GIMLET SHAPE."

It may do well enough for Boyd, but Caldwell, being a "Professor," has nothing to do with gimlet-pointed lightning. According to Caldwell, electricity is "ejected from the Battery in a circular current, similar to the action of a ball after being shot from a rifle, and enters the system in that shape, twisting and turning until it has spent its force." Uncharitable persons might say that with the exception of substituting a rifle-ball for a gimlet, that this reads just like Boyd's circular. But great geniuses often hit upon the same ideas. Our readers can now have their choice. Those who prefer their gimlet-pointed will take Boyd's, but if they prefer to have it "twisting and turning" in rifle-ball style, Caldwell's is the battery for them. Sensible people will let all these batteries alone, as the most useless humbugs of the day.

"Pussly."—This plant, which is with some the type of meanness, is known botanically as *Portulaca oleracea*, and is a near relative of the beautiful *Portulaca* of the flower garden. The range of this weed is a large one, as the following names which it bears in different countries show. In Germany it is known as *Portulakkraut*, in France, *Porcellaine*, and *Pouppier*, in Italy, *Porcellaria*. The spelling of the English name has varied some; as for example, the old English writers have *Porcellaine*, and *Porcelayne*, but with us, while a few say *Purslane*, the name is generally shortened down to simply "Pussly." Whatever the name, or the spelling of the name, of the plant may be, it remains the same rapid growing, plump and low spreading weed, that it was centuries ago, when it was called *Porcella*, the diminutive of *porcus*, a pig, probably on account of its greedy feeding and quick growth. Still it is not all bad. As a weed it is a great promoter of industry; a gardener must be wide awake during the hot weather, or "his 'pussly' will get ahead of him." Its seeds are very pretty when magnified, and as a table vegetable, it is not to be despised. The plump succulent stems with their leaves, are boiled tender, and dressed with butter the same as spinach. The French market gardeners cultivate it regularly, and have different varieties.

Keeping a Record.—A habit of noting the ancestors and date of birth of the larger stock of the farm, even though it be not "full blood," is a useful one. If a record is of so much value for the best stock, it is at least worth the keeping for the good grade cow, or the mixed bred horse. It is often a great convenience to know to what animals a cow in question traces her parentage, and it may be of money value to be able to show the record.

Time to Cut Timber.—July and August are the best months for cutting timber, that it may be the most durable. The growth of the year is now well nigh over, and if the trees are allowed to lie until the green foliage dries upon them, the greater portion of the sap is thereby withdrawn from the wood and the seasoning is rapid and perfect. Cut in mid-summer, insects are much less liable to attack the wood, which is an important point with some kinds of timber like the hickory, etc.

Angora Goat Company.—The Legislature of Virginia, has recently granted a charter for the incorporation of a company, to be known as the "Virginia Angora Company." Up to the present time in this country, the growth of the Angora goat has not been a source of very great income to those thus engaged, but with a considerable demand for the goods made from the hair of this goat, and the admirable adaptation of portions of Virginia to the animal, we may reasonably anticipate a profitable issue to the new impetus given to the Angora goat enterprise.

The Cow Essay.—We wish our readers interested in the keeping of one or more cows—and the list must be a long one—would read the capital essay given on page 270, and see how thoroughly practical it is from the beginning to the end—how full of valuable information in all its parts to the thousands interested in good milk.

How to Use Hen-Manure.—Dry muck, loam, or other earth, will retard or prevent the fermentation and hold the ammonia that is formed. Water enough to keep quite wet will do the same in cool weather. Plaster with enough moisture will also absorb the ammonia, but dry plaster will not. The custom of mixing lime and ashes with hen dung is wrong. They drive out the ammonia instead of holding it. Mouldiness implies, and

smell of ammonia (heartsborn) proves, decomposition and loss of ammonia. But the smell of ammonia is extremely pungent, and unless it is very strong, not much loss need be feared. Since the chief fertilizing ingredient of hen dung is nitrogen, and it has so little phosphoric acid and potash, it is rather a stimulating than a lasting manure. Many farmers use it for corn. But nearly all of our experiments (see *American Agriculturist* for March, April, and May) imply that this is poor policy, since corn gets but little help from nitrogen and responds best to phosphoric acid and potash. A little in the hill, however, well mixed with earth, may be very useful to give the crop a start. Hen dung is useful for potatoes, garden vegetables, or indeed almost all crops, including strawberries and other small fruits.

The Horse Fork Neglected.—While the excellent labor-saving machinery for sowing, caring for, and cutting the farm crops, have been very generally appreciated and employed, the means for placing the grass and hay in the barn, have been far too frequently neglected. The improved and almost perfect horse forks have claims upon the farmer, that he is slow to acknowledge. We used to think the hardest work of the haying and harvesting was the "pitching off," but when we put up one of those grappling forks and set it at the work, with a horse as the power, the hard labor was changed into a sort of half sport. The horse fork is one of the great recent inventions, and deserves to take a front rank among those machines that lighten the labor of the farmer, and at the same time allows his work to be done in the most rapid manner in that portion of the season when he is the most hurried and every aid is appreciated.

Cultivated Wheat and Hessian Fly.—It is now a well established fact, that the Hessian Fly is much less troublesome on wheat that is sown in drills, between which the cultivator is passed now and then during the early growth of the grain. Two fields of wheat growing side by side, one of which is cultivated and the other not, but alike in all other respects, seem strong proof of the truth of the above statement.

Red Ants, one of the worst pests of the household, may be trapped by placing a greased plate where the ants can get to it, when in a short time it will be covered with the ants adhering to its sticky surface. The ants may be wiped off and killed, whenever the plate becomes covered, and the trap set for another "catch."

Heavy Pigs.—"A. T. H.," Reusslaer Co., N. Y., seeing a notice of some heavy pigs in the February number, sends an account of others worthy of mention. On March 13th, 1883, Mr. Thomas Hoag, of Tomhannock, N. Y., had from a sow of his own breeding, 10 pigs, of which the combined weight was 35 pounds. In looking them over a few days after, he concluded to see what he could make of them. He kept an accurate account of all feed given, except the sour milk from four cows, even charging them for their pasture and the old wood used in cooking their food. On the 15th of December he killed them and sold them in Lansingburgh for \$7.50 per hundred weight. The aggregate weight was 4,241 pounds, averaging 424 pounds. The account stand as follows:

DR.	
To 10 pigs seven weeks old.....	\$30 00
" 212½ bush. corn at 75c.....	159 37
" 36 bush. oats at 45c.....	16 20
" grinding.....	14 78
" 13 bush. small potatoes at 12½c.....	1 63
" 6 loads pumpkins at \$1.....	6 00
" pasture.....	3 00
" wood.....	2 00
Total expenditure.....	\$232 98
CR.	
By 4,241 lbs. pork at \$7.50 per hundred.....	\$318 07
Balance.....	\$85 09

As you will see, they were only nine months and two days old. They were from the best breed of swine that he could procure in his neighborhood at that time, which was before the era of the large improved breeds. Mr. Hoag proclaimed at that time that whenever his weights were beaten, under like circumstances, he would try again, but he has waited long and has seen the snouts of nearly 80 winters, yet he believes he still remains the champion of heavy weights, as he has seen no authenticated report to the contrary.

The Tide of Emigration.—It is an interesting sight to see Castle Garden—which is not a garden, but a great building—filled with new comers from all parts of the world. During the month of April, there were no less than 46,148 emigrants landed, this being the largest number that has ever come to our shore in the same space of time, and this does not include the many that come over in the cabins of the steamers, and go at once to their friends. The emigrants, as a whole, appear to be of the hard working class with but little capital, they mostly go

to the great west, where they will undoubtedly make a working force that will be welcome, and their zeal in seeking a new home appreciated.

**Barn Weevils.**—These are not, as some suppose, brought into the granary in the wheat. It is an insect that attacks the grain only after it is harvested. A new granary should be so constructed as to afford no crevices to harbor the insect, and the door and other openings should close so tightly at every point that the weevil can not enter, and whatever spaces are to be left open for ventilation must be covered with wire gauze, fine enough to exclude it. In France, the receptacles are often built of sheet-iron. In an old granary, known to be infested by weevils, there is but one safe course, which is to store the grain elsewhere for two years, at the end of which time the weevils will be starved out. "W. K. W.," Lancaster Co., Pa., writes us that in two cases within his knowledge the insects have been starved in this manner. If the wheat is threshed in the barn, care must be taken to leave no scattered grain, and straw is to be stored in the barn only in case it has been thoroughly threshed.

**Values of Manures from Feeding Stuffs.**—"W. G. L." Mr. Lawes, the famous English experimenter, has calculated the money values of the manures produced from different foods by assuming that certain percentages of nitrogen, phosphoric acid, and potash are consumed and lost, that the rest go into the manure, and that in the manure they have there about the same value, pound for pound, as similar ones in commercial fertilizers in which their value is pretty well settled. Below are Mr. Lawes' valuations of the manure from—

Cotton-seed meal, one ton.....	\$27.86
Linseed cake, one ton.....	19.72
Beans, one ton.....	15.73
Wheat bran, one ton.....	14.59
Clover hay, one ton.....	9.64
Indian meal, one ton.....	6.63
Meadow hay, one ton.....	6.43
Oat straw, one ton.....	2.90
Potatoes, one ton.....	1.50
Turnips, one ton.....	.86

This matter has been much discussed. Dr. Velcker considers Mr. Lawes' valuations, in general, from thirty to forty per cent too high, and evidently on good grounds. Of course, the worth of the manure is modified by numerous circumstances. Growing or fattening cattle or milch cows will retain more of the nitrogen, phosphates, etc., from the food and leave less in the manure than store cattle. The waste before the manure gets on to the land varies in different methods of treatment. But nevertheless the figures give a fair idea of the relative values of the manure made from different fodder materials. For farmers in the older States, who buy commercial fertilizers, a deduction of one-third from Mr. Lawes' figures would probably be not far out of the way.

**Coal Oil Barrels.**—Suggestions as to the cleansing of these continue to come. "B. J. G.," Naples, Iowa, and "M. L.," Lansing, Pa., both advise long continued soaking in water, the idea being that the water enters the pores of the wood and gradually displaces the oil; the first advises sinking the barrel in a stream, the other to set it under the eaves and keep it filled with rain-water. "H. W.," Excelsior, Mo., suggests keeping the barrel full of rain-water, adding the wood-ashes as they are taken from the fire. Neither state how long it will take to remove all traces of oil, and all suggest putting the head that was removed edgewise in the barrel.

**Water for a Bath House.**—"E. S.," Orange, Tex., asks what would be the cheapest method of pumping and heating water for a bath house. If the water is to be raised from a well, a windmill would be the cheapest. The heating of the water will depend upon the quantity. If much is to be heated, it may be best done in a wooden tank, by means of steam driven into it. If a steam boiler must be put up for heating the water, then in such a case it may be better to have a steam pump to raise the water, and use the exhaust steam for heating.

**Millet and Abortion.**—"J. R. E.," Somerset, Kansas, writes that it is a general belief in his vicinity that common millet will cause abortion in mares; he has three mares in foal and no other hay, and would know if it is safe to feed it. We do not think it possible for millet to cause abortion directly. When it is cut too late, the bristles that grow near the seeds become dry and hard, and cases have been known in which these bristles had matted together and formed a large ball which ultimately caused death. Should this occur even in a small way in a brood mare, her general health would be affected, as it might be from a score of other causes, and abortion follow at a matter of course.

**Raspberries and Blackberries.**—W. C. Steele, La Porte, Ind., who has had much experience with both these fruits, prefers to keep the canes much shorter than is usual. He finds that 18 to 20 inches for

Raspberries, and 24 to 30 for Blackberries is better than a greater height. He claims that the bushes are not liable to be blown over, that he gets just as much fruit, and that it is easier to pick, especially if the pickers are children. The stopping should be done when the plants reach the height named, by merely pinching out the young and tender growing point with the thumb and finger.

**Boulders in Oregon.**—"C. M. C.," Benton, Oregon. Geologists account for the appearance of such boulders by supposing that at some former period the earth in the locality was covered with ice, and that glaciers, or rivers of ice, were moving, carrying vast amounts of earth, stones, etc., as they are now known to do in the arctic regions and in the Alps. The fact that the stones your mention are very smooth, as if they were polished, gives support to this view of glacial action.

**Locusts in West Va.**—"W. C. S., Jr.," Volcano, W. Va., writes that this is the year of the appearance of their brood of 17-year Cicada, and that there is scarcely a foot of ground without a hole from which an insect has come out. He finds that the song of the Cicada becomes somewhat monotonous, and compares it to a "ringing in the ears." To our notion its sound is more like that of a threshing machine at work at a distance. We have seen it stated that after their long career in the soil, the insects cease to do mischief, and in the winged state are harmless. This is an error. The female lays her eggs in grooves cut in the small branches of trees; these are often so numerous as to cause the death of the twigs and branches, which, after a time, are broken off by the wind and fall to the ground. They seem to prefer the oaks to other trees, but will deposit their eggs on any others except those of the Pine Family. When they select fruit trees, much damage often results to the orchard.

(Basket Items continued on page 285.)

### Reform in English Agriculture.

Mr. Caird, an authority on British farming, instead of grieving at American competition, advises the English farmer to make some radical changes in his system, and engage more extensively in the production of those commodities, that do not admit of either long storage, or carriage; such as those of the dairy, market garden, etc. He says in a letter to "The Times," (London):

"The introduction of foreign meat and cereals is of immense benefit to the consuming classes of Europe. American statesmen believe they are rapidly gaining control of this trade, and can maintain it even at lower prices. It must be met by the production here of articles which will not bear long storage or carriage, such as milk, fresh butter, early vegetables, meat, hay, straw, potatoes, and the sugar beet. Grass farms, dairying and market gardening—all the interests in land, whether of the owner, occupier, or laborer—must be disenthralled. The control of the dead hand must be removed. The sale and transfer of land must be simplified and cheapened. Enumbered and unwieldy estates will then be broken up and subdivided to form numerous small properties.

"The drain of agricultural labor and capital to the United States and Canada, which has already commenced and which nothing can prevent from continuing and increasing, will alter the existing conditions of agricultural property in England. Our agriculture must adapt itself to the change, freely accepting the good it brings, and skilfully using the advantages which greater proximity to the best market must always command."—This is a very clear and thoughtful statement of the whole trouble in English agriculture, with a way out of it, that the wise farmer must see is the proper one.

### Good vs. Poor Hay. When to Cut Grass.

There are two radical defects in the ordinary practice of growing and harvesting grass and clover. The soil is poorly manured and poorly tilled, and the grass is allowed to get too ripe before it is cut. It is abundantly proved, by actual analyses, that grass grown on land in good condition, is not only larger in quantity, but better in quality, richer in albuminoids, the most valuable food-ingredients, than that grown on poor soil. As to the best time for cutting grass and clover, the experiments described by Prof. Atwater, under the head

of "Hungarian Grass," in the present number, coincide with the best data from foreign sources, in implying that early in the time of blossom, or from a little before that to full blossom, is, on the whole, the best period for cutting grass and clover. The hay thus obtained is easily digestible, and has a good percentage of albuminoids. But as it grows older, the proportion of nitrogen decreases, and that of woody fibre grows larger, the hay becomes less digestible, the digested material is poorer because it lacks albuminoids, and finally the hay is not so palatable. For all these reasons, the late cut hay is worth far less for feeding. Timothy and clover grown on rich land, cut early, and well cured, make excellent fodder. Grown on poor soil, and cut late, they are pretty poor stuff. A great deal of the hay that lies in barns throughout the country, is little better in feeding value than good straw.

### An Improvement in Churns—The Blanchard.

The churns in common use, operate in two principal methods. In one, the cream is beaten with something, and in the other, something, so to speak, is beaten with the cream. Of the first class are all the various dasher churns, in which agitation is produced by the alternate up and down motion, or the continuous or revolving motion, of a variously shaped piece known as the dasher. In the other set, the something beaten with the cream, is the sides or interior walls of the churn. The cream is dashed against the churn, by revolving a rectangular box, or by giving a similar box a reciprocating swashing motion on an axis, or in a tin cylinder, by means of an oscillating, or pendulum movement. The devices in both classes of churns, for effecting a simple object—the agitation of the cream, are most numerous and varied. The first named class—the dasher churn—is more generally used than any other, and no churn in this class has acquired a wider or higher reputation than the Blanchard. In this there is a revolving dasher, of

THE IMPROVED BLANCHARD CHURN.

such a form—though very simple, that it not only accomplishes the churning with great rapidity and completeness, but allows of the gathering and partial working of the butter before it is removed from the churn. The great claim made by the makers of the various oscillating or swashing churns, in favor of their method is, that the cream is all acted upon equally, and that no portions of it can escape agitation, and be less completely churned than the rest. The Blanchard churn, as originally made, was semi-cylindrical, with a flat top; the small portion of cream thrown against the under-side of the top at the beginning of the operation might, if left there, be imperfectly churned, and if this were mixed with the butter at the close of the operation, that might be streaked or specked. But only a careless dairy woman would leave the cream thus; no matter what kind of churn was in use, a stone-jar, or a Blanchard, a careful butter maker would make sure that the cream was all churned alike, and by scraping down occasionally the small portions that were thrown against the sides, top, etc.,

obviate any trouble from this source. Recognizing the fact that, in their churn as originally constructed, those who tried to do so, could allow a small portion of cream to escape churning, they have modified it so as to make the interior a complete cylinder. The improved Blanchard has a curved top instead of a flat one, and now appears as in the accompanying engraving. We never had the least difficulty in many years use of the churn in its former shape, but as the present form prevents all trouble from unchurned portions in the hands of any one, the change is an improvement. No alteration has been made in the other parts of the churn, and it does not appear that any improvement is possible in these, whether we regard their effective work, or the ease with which they may be taken apart and kept clean, both important features.

### The Army Worm—Its Habits.

On the first day of June, Mr. J. N. Plumb, who has a farm at Islip, Long Island, called to say that his grain fields, and those of his neighbors, were being devastated by the Army Worm, and wished to know something of its history, and what remedies had been found useful elsewhere. Knowing that the name was applied to at least three other caterpillars, all of different habits, we requested

Fig. 1.—THE WORM, FULL GROWN.

specimens in order to be sure of the identity of the insect in question. The prompt arrival of specimens of the insect with those of the rye upon which it had been at work, at once settled the fact that the Army Worm was upon Long Island in force, and soon after accounts were given in the daily papers. A letter from Mr. J. M. Budd, dated June 4th, announced that the same insect had appeared in force "on the neck lands of Kent Co., Del.;" that some wheat crops were diminished by one half, and asked

that we give an article for the future guidance of the farmers in that locality.

The earliest recorded appearance of the Army Worm in the Eastern States was in 1743. Next, in 1770, it was present in great force in New Hampshire, and some other parts of New England. Their next serious raid was in 1817, in Eastern New York and Western New England. From that time until 1861 it was not troublesome; in 1875 it appeared in parts of New England and on Long Island, and now, after an unusually brief period, it again parades in the last named locality. During the years since 1861 it has appeared in destructive numbers in several of the Western States, notably in 1861, at which time it extended from New England to Kansas—and in 1875 it visited a large part of Missouri.

We can best serve our readers by giving a condensed description of the insect and its habits. The best history is to be found in Riley's Reports as Entomologist to the State of Missouri: the 2d (1870), the 8th (1876), and the 9th (1877)—that in the 8th being especially full. We may say, in passing, that while the State of Missouri, with a short-sightedness utterly at variance with her former intelligent liberality, has abolished the office of State Entomologist, the country at large is greatly indebted to her for the work already done by Prof. Riley, and his nine Reports contain the most useful information anywhere to be found upon the insects there treated of. The facts and the engravings here given are mainly derived from this excellent source.

### The Insect Described.

The full grown Worm is of the size shown in fig. 1, and has a general dingy black color; Riley describes its markings thus: "On the back a broad dusky stripe; then a narrow black line; then a narrow white line; then a yellowish stripe; then a narrow sub-obsolete white line; then a dusky stripe;

then a narrow white line; then a yellowish stripe; then a sub-obsolete white line; belly, obscure green." The head is pale grayish yellow. When

Fig. 3.—THE MOTH, NATURAL SIZE.

full grown they suddenly disappear; they enter the earth, form a cavity a few inches below the surface and change to the chrysalis (fig. 2), "of a shining mahogany brown color, with two stiff converging thorns at the extremity, having two fine curled hooks at each side of them." In two or three weeks the changes are complete, and the perfect insect appears as a moth, given of the natural size in fig. 3. The general color of the moth is light-reddish brown or fawn color, this is sprinkled with minute blackish atoms or spots; there is a dusky line running inwardly from the tips of the front wings. Near the center of these wings, towards their upper margin, is a white spot, which allows the moth to be distinguished from others, and from which it derives its specific name, the insect being known to entomologists as *Leucania unipuncta*.

### How Does it Pass the Winter?

Many, indeed the majority of moths are short-lived; depositing their eggs soon after they issue from the chrysalis, their career is completed and they die. With the moth of the Army Worm, Prof. Riley found the eggs very immature when it was some weeks old, and his observations lead to the conclusion that it does not deposit its eggs until the following spring, but in the fall finds some crevice in which to hide itself to pass the winter. The same naturalist thinks that some of the insects pass the winter in the ground in the chrysalis state, especially in northern localities. The moths, after their winter's rest, appear in the spring soon after vegetation starts, and deposit their eggs in April. The eggs are opaque, white, spherical, and  $\frac{2}{100}$  inch in diameter; these are deposited in clusters of 5 to 20 upon the stems of grass, or rather along the base of the uppermost leaf of the grass stem, and glued in place. The eggs hatch in 8 or 10 days, and the minute, newly hatched insect is white. The caterpillar, during its early life, is greenish and not noticeable; it is only when it has changed its skin several times that it begins to show the characteristic markings that distinguish the full-grown worm.

### What It Feeds Upon.

Such, in brief, is the history of the insect from the egg around to the egg again. Its natural food is the coarse wild grasses; among cultivated grasses they are most fond of timothy and blue-grass; clover they do not like; wheat they are especially fond of, more so than of rye, though they will eat that, as they will a variety of other plants when pushed. The preference of wheat for rye was manifested by the worm in Missouri. Since this was in type, Mr. Plumb has informed us that the preferences of the Long Island insect are exactly the reverse, and that it greatly prefers rye to wheat, which it will leave if rye is near by. Accounts from Delaware state that there wheat is the crop most injured. The insect will attack corn, but not potatoes or pumpkins. Hogs, chickens, and other poultry devour vast numbers of the worms, as do the wild birds and other animals. Hogs are said to have eaten so greedily of them as to die in consequence. Like most other insects, these have their insect enemies, both cannibals, which destroy the young larvæ, and those which themselves pass their larval state within the bodies of the larger caterpillar or Army Worm. Such parasites work unnoticed, save by the few naturalists who study their habits, but they render important service in keeping these and other destructive insects in check. In Army Worm years the worms are not noticed during their early life; and it is only when, after having destroyed the grass on the field where they were bred, they start

out in search of food, that they become formidable. Their course in one direction, taken by all through some mysterious common impulse, is held with remarkable tenacity. If shallow water is met, the advance fall in until their dead bodies form a bridge for the living ones to cross.

### Methods of Destroying the Worm.

Upon a road or upon a fairly level field large numbers of the worms can be killed by the use of a roller. Crude petroleum has been suggested, and we have no doubt that vast numbers might be killed by watering a strip, especially where they would cross a road, with this. The worms in crossing a belt of the petroleum would probably get sufficient upon their bodies to kill them. Another method is to poison a strip of grass in their path with London Purple or Paris Green, in the same manner as potatoes are dosed for the Potato-Bug. To save a field of grain from their attacks the most effective method is to make a trench by plowing, running two or three times in the furrow, with the straight side towards the field. When a large number of the worms are collected in the trench, straw may be strewn along it and set on fire; the heat not only kills the insects, but keeps the side of the trench dry and crumbly, and prevent them from climbing it. If a heavy rain should wash the side of the trench, it must be mended or a new one plowed. It has been suggested to dig pits or small wells in the bottom of the trench at intervals; the insects in going along the trench in search of a place to ascend the side, will fall into the pits and be trapped in large numbers; when the first set of these pits is nearly full, other pits are dug, throwing the earth into the first ones to kill the worms. It has also been suggested to feed the worms in the trench with freshly cut grass that has been thoroughly sprinkled with London Purple or Paris Green. It may be some satisfaction to those who have suffered from the visitation of the insect, to know that two successive Army Worm years have never been known in any one locality, and it is not thought that such can occur. They are with us more or less every year, but it is only when conditions favor an unusually abundant crop of them that they become troublesome. It has been observed that the worm usually appears in wet springs that have been preceded by one or more very dry years. As to the time of their appearing, that is, in destructive force, it is found in the different localities to correspond very closely with the period at which the wheat is in "the milk."

### Experience with Barbed Fence.

C. L. Sanborn, Sup't. of "Sawyer's Ranch," Silver Lake, Kansas, writes to the *American Agriculturist*: "I have been very much interested in the various articles on 'Fences and Fencing,' and, as requested, will give you our experience with wire fence. Within the last year we have built eighteen miles of wire fence, using both plain and barbed wire. We have seven miles built of two-barbed, one plain wire, and board at top. This makes a very good fence, but we now think the board should be between the barbed wires. We have three miles of fence composed of four plain wires, one foot apart, the two middle ones being barbed after putting up. This fence we do not like, as the bars slip on the wire, and stock will slip through. Another three miles is built of three-barbed wires, 16 inches apart. This makes a good fence for large stock, but for yearlings and calves the wires should be nearer together. The best fence we have is built of three steel-barbed wires, bottom one 18 inches from the ground, the others a foot apart. For posts we use wood—cedar, oak, black walnut and elm—which we set in the ground two feet, and 8 to 20 feet apart. Oak posts are liked best, as they hold the staples more firmly. We have used the 'Glidden's' Steel Barbed, the 'Steel Barbed Cable' Fence, the 'Ohio Steel Barbed,' and 'Lyman Manufacturing Co. Barbed Fence,' and now give preference to the last named.—We never have had stock of any kind injured from running into the wires. In fact cattle will have nothing to do with a good steel barb.—Our fence costs from 50 cts. to \$1 per rod. Posts cost 10 to 14 cts. each.—The fence we have built

Fig. 2.  
CHRYSALIS.

encloses a stock farm or 'ranch' of 3,000 acres, and we consider steel-barbed wire fence, with oak or iron posts, the best fence for Kansas.—In putting up the fence, we run the wire off from the spools, from a wagon, stretching from a half to a mile at a time, with blocks and tackle. Corner posts should

Fig. 37.—A POST BRACE.

be well braced. The best plan is to bore two holes in the bottom of the post, and drive two-inch sticks through (as shown in the sketch, fig. 37). These posts, well put into the ground, and braced from the top wire, can not be pulled over.—[In fig. 38 we suggest a simple method of bracing corner or stretching posts which will frequently be convenient. At a distance of 4 to 6 feet drive a short stake of a length required by a loose or compact soil. From this extend a short wire, or a double one, to the post. Where there is much strain, this wire will need to be heavy, or it will break or stretch. If needed, a bracing wire may be put on each side, as shown in the engraving, fig. 38. These short stakes will not be in the way, as they will be directly under the running fence. The horizontal wires may

Fig. 38.—METHOD OF BRACING THE POST.

be given one turn around the post, and a staple driven to prevent slipping up or down, or they may be put through a hole bored in the post and securely fastened by driving in a spike or large nail. ED.]

R. A. Steele, of Douglas Co., Kansas, writes to the *American Agriculturist*: "I have been using barbed-wire for the past year; was previously prejudiced against it; have now over one mile—three wires, with posts one rod apart. It answers the purpose; that is, it turns stock. I had in pasture over 200 Colorado cattle, last year, 'stampeded,' and they broke the fence once only. Stonewall is the fence for this region; costs \$1.25 per rod, and turns hogs, etc. We consider barbed-wire fence, when properly constructed, safe, but not so cheap as stone.—My plan in putting up wire is: posts one rod apart, every tenth post to be well set, to strain the wire. Use a clamp around the wire attached to a lever; fasten to the first post, and roll out to the tenth post, apply the lever, and draw the first wire, which should be the lower one, the tightest (no team can equal this way); put the remaining ones on the same way, but not quite so tightly. It will not do to tack wire on to trees, unless you first nail on a strip or board, which will save the wire from rusting and breaking, as it would do in a few years. I have seen this tried, and it is no theory.—In a word, poorly constructed fences are the ones which usually cripple and maim stock. I would recommend the posts not over ten feet apart. Where timber is scarce, plant an osage orange between the posts, and let them grow to make a small tree, and when of sufficient size, saw off say five feet from the ground, nail on a strip to fasten the wire to, and you have a post which will last. This is the only use I would have for osage orange. I prefer the four-barbed rather short; the long ones cut severely. I have no interest in any particular wire, but have my preference, and my object in writing to you is, this wire fence is bound to be the rage, and for certain localities, will be the only fence, provided they can suspend it in the air; but for a large portion of Kansas, stone is so convenient that it is far cheaper; the only thing is time.

With stone fence we can let hogs run, which is a great consideration. Six wires may turn hogs, but I doubt it—that is those that are quite small."

### More About the Army Worm.

The appearance of the Army Worm in several eastern localities has caused no little excitement; the daily papers have had articles, some of them more or less sensational, and the inquiries made of us both in person and by letter show a general desire for information concerning this pest. A condensed history of the insect will be found on another page. After that article was in type we received from Mr. J. N. Plumb copious notes of his observations of the insect, and its habits, and a very full account of his battle with the "Army," in his attempts to save certain crops from destruction. "Deer Range" farm, Mr. Plumb's place near Islip, L. I., enjoys the distinction of having been the first locality on Long Island, visited by the worm—or at any rate, the first on which it was noticed. To publish Mr. Plumb's article entire would be to repeat much that is given in the article referred to; we only give points which are not already stated.

#### How they Move.

"The Army Worm is still working north and west, and seems to have no inclination to go east—the dividing line of their destructive work is so marked, and well defined, that at a distance of 10 feet to the east—without any barrier to prevent—not one worm can be found. In the potato field which lays along the 40 acres of rye, they have never gone east further than the tenth row.

#### "Their Favorite Food

seems to be rye, corn, red-top, and timothy, especially the two latter. It is the impression of my manager, Mr. Jarvis H. Smith, that they will attack and eat wheat if in the line of their march. They prefer rye and will leave the former for the latter if near by. Any kind of grass they will devour—if they can find any green and tender to feed on near by—but when everything else is consumed, they will go back on to the clover and make clean work of it.

#### Crops May be Saved.

"Directly north of the destroyed rye field, separated by an avenue two rods wide, is a field of 21 acres of corn now eight inches high. All our energies were directed to keeping them out of this field, and a large field of potatoes adjoining, as they were directly in their march to the north. It has been a hard week's fight, as all hands here know, but we have succeeded thus far in saving those two crops.

#### Attempts to Stop Them.

"We dug deep trenches, used Lime, Salt, Paris Green, Tar, set fire to the grass, and where there was no grass, carted hay, etc., and set fire to it in windrows, and with a large staff of men could not head them off; nothing would stop them. They had got the start of us, were headed west and bound to go west, and when the ground was hot and scorched after burning the grass, they marched right along over their dead and dying comrades that went before, stopping for nothing. My son set fire to the grass when they were crossing and they marched fearlessly right up to the very edge of the burning grass, never turned back, but as they shrivelled, others walked over them and while the ground was hot and smoking on they came.

#### Success in Poisoning.

"As for trenches or deep furrows we found them of no protection of themselves. But we finally conceived the idea (after burning hay, sprinkling lime and tar in these trenches without avail) to put in these trenches, their favorite food for them to eat—viz. red-top grass. This grass we wet with a mixture of Paris Green, the same that we use for potato bugs. And as long as the grass remains green and fresh they will remain quietly in the trench and feed on it and it kills them by millions, but as soon as the grass gets dry they stop eating it and then go out of the ditch if they can. (London Purple has the same effect as Paris Green). From this time forth we shall adopt this plan as the most effective; killing more and with less labor.

### When they Feed.

"Our experience is—and we have studied their movements very closely—that their principal feeding time is from 11 A.M. until sundown. At 3 P.M. they seem to be more numerous than any other hour of the day. Early in the morning scarcely any are to be seen; they are then in companies of 25 to 50 secreted in the sods, tufts of grass, roots, clumps, or wherever they can get protection or shelter. As soon as the sun comes out warm they begin to move, the companies form in line and the march goes on. They never fail in discipline, never encroach upon the rights of each other—and in feeding are careful not to crowd each other and never contend for the same blade of grass. It is rare to find more than one on a stalk of grain. We are satisfied they do not feed or travel much at night—as I went out at 1 o'clock A.M. with a large reflecting lantern, and after a careful inspection found but few on the stalks of grain. They were on the ground and did not seem to be feeding any, and but few were travelling." A day or two later Mr. Plumb sent us another report from the "seat of war," from which we extract the following concerning the

#### The Use of Trenches.

"In reference to trenches, ditches, or deep furrows to head them off, I would say that a ditch or trench is of no avail if after it is made it is left to itself. It must be constantly watched by men or boys, walking up and down along the trench, and sweeping back the worms as they crawl out, but the plan you sent me we found the best of all the methods we tried (and we have tried everything that ingenuity and energy could devise) and that was to dig pits every rod or so in the bottom of the trench. In this way we have caught and destroyed untold millions. The worms in their determination to go north approach the trench and go or fall into it. Then they attempt to go out on the opposite side—finding it not easy they, after several efforts, work along the trench in the endeavor to find an opening, and in doing so fall into the pits arranged along the bottom of the trench and which we dug about 2 feet deep and a foot or more square, with straight, clean shaved sides. In this way we have in a few hours time reduced the rank and file of the Army Worm in fearful numbers, and is the only plan I have any confidence in. Plowing a furrow is of no avail or use whatever in checking the progress of the Army, if, after plowing, a spade is not used to deepen and throw out the loose dirt at the bottom and sides; but on a big farm this is costly work."

### Science Applied to Farming—LVIII.

#### Hungarian Grass and Hay.

I have received inquiries from a number of States, concerning the composition and nutritive value of Hungarian Grass. Some analyses and comments bearing upon the question, were published in the "Report of Work of the Middletown, Conn., Experiment Station, 1877-8," but as the circulation of this was limited, an outline of the results may be in place here. The samples analyzed were from Aravana Farm, Middletown, and kindly furnished by its proprietor, Dr. J. W. Alsop, with the following descriptions.

**SOIL.**—Low land, gravelly loam, stony, clay subsoil, wet in spring. Had been unbroken pasture for at least twenty years, until fall of 1874, when it was under-drained three feet deep, (drains forty feet apart), and plowed. In 1875 had roots in drills, with a liberal supply of barn-yard manure.

**CROP.**—In first week of June, 1876, sowed to Hungarian grass, applying the Stockbridge formula for Hungarian for one ton. Crop cut July 17, 1876. Yield about 3,300 lbs. of Hungarian hay per acre.

**SUBSEQUENT TREATMENT AND YIELD.**—Pastured until Aug. 18, 1876, then plowed and seeded with herd's grass, red-top, and clover, with dressing of 200 lbs. of blood guano per acre. In 1877 cut from the three acres, three rods, and twenty-seven rods, nine loads of hay, averaging fully one ton per load, and two loads of clover rowen. In 1878 cut eleven loads of hay and three loads of rowen. The samples for analysis were taken from plots of 49 to 87½ square feet area, as follows:

No. I. Cut July 17, 1876. Heads partly filled; seeds little developed; stalks averaged about twenty inches long.

No. II. Cut Aug. 3d. Heads well developed and well-filled with seeds; seeds soft; hay rather

yellow; stalks averaged about twenty-six inches long.

No. III. Cut Aug. 18th. Nearly ripe. Heads well-filled, seeds falling out; hay coarse and yellow like straw; stalks some thirty inches long.

The yields per acre of the freshly-cut grass, cured hay, and dry (water-free) substance, as calculated from the yield on the small plots, which of course do not represent what would be the produce per acre, were as follows:

No.	Green Fodder.	Cured Hay.	Dry Substance.
I.	July 17, 1876....20,740	July 29, 1876....5,876	4,509
II.	Aug. 3, " ....16,891	Aug. 12, " ....6,111	4,778
III.	Aug. 18, " ....10,454	Aug. 25, " ....4,014	3,121

The percentages of water in the freshly-cut grass, were: I, 78.3; II, 71.7; III, 70.2; in the freshly-cured hay: I, 23.2; II, 21.9; III, 22.3. On standing, they dried down still more. The crop on the whole field, 3,300 lbs. per acre, cut July 17th, would be, per figures of I, assuming 75 per cent of water in the grass, and 23 per cent in the freshly-cured hay:

Green Weight, @ 75 per cent Water.	Cured Hay, @ 23 per cent Water.	Dry Substance.
10,164 lbs.	3,300 lbs.	2,511 lbs.

**The Composition of Hungarian Grass & Hay.**  
Analyses of the samples at our laboratory gave results as in the table below, in which I add German analyses by Moser and Metzdorf.

HUNGARIAN GRASS AND HAY.

6.7	38.8	0.8	6.1	0.67	1.03				

It appears that Dr. Alsop's Hungarian grass cut in blossom agrees exactly with Wolff's average for German, both being reckoned on basis of 75 per cent of water. Dr. Alsop's hay in the table falls a trifle below the German. This is because it is reckoned on basis of 16.7 per cent, one-sixth, of water, whereas Wolff assumes only 13.4 per cent. Like other grasses, the Hungarian as it grows older has less albuminoids and more woody fibre. At the same time, it becomes less digestible. The Hungarian hay, No. II, is worth about one-fourth less, pound for pound, according to the calculation, than No. I. The youngest hay, with one pound of digestible albuminoids to 6.7 lbs. of carbohydrates is a good fodder, but the old hay, No. III., which has only one pound albuminoids to 14 of carbohydrates, is

poor; it lacks material to make flesh, fat, and milk. Dr. Alsop's Hungarian hay, cut in blossom, is just about equal to the average German meadow hay (English grasses), which is equivalent to saying it is decidedly better than average upland hay with us, as may be seen from the analyses of American hays, (M. M.) in the table. Our hay suffers in comparison with theirs, because we do not manure or till our land so well, and often cut our grass late. For these reasons much of the hay cut on our old meadows is little better than good straw.

Dr. Alsop's crop of Hungarian was not large. Cut early in blossom, the yield on the whole field fell short of two tons of hay per acre. But it made excellent fodder, and the land was in good condition, so that in the two succeeding seasons, it brought six tons of good hay and rowen, and promises to continue to do well for some time to come. Let us now consider the matter of

**Hungarian in General.**

Those who know the most about Hungarian grass, ascribe to it two chief peculiarities, deep rooting and rapid growth. Being a deep feeder it stands drouth, and often brings very large crops in soils and seasons where other grasses would fail. It requires, however, a rather loose soil with not too compact sub-soil, doing best on sandy loams and the like. Humus and lime are said to be favorable to its growth. The soil should be deeply plowed and well tilled. On account of its deep feeding Hungarian is said to exhaust the upper layers of the soil less than other grasses. It does particularly well on newly broken land or after a hoed crop like corn, potatoes, or roots. Being a rapid grower, fresh dung is said not to be so good for it as well rotted manure or concentrated fertilizers. It wants a good supply of available food in the soil. It may be sown at any time from May to August, its rapid growth permitting it to be cut early and cleared away for a fall crop, or sown late to piece out the scanty fodder of a dry summer or fall. Cattle are said not to relish it so well when cut too young. At the same time if it stands too long it becomes coarse, strawy, and indigestible. I have no data at hand to show how large crops are generally obtained with us. European figures put the yield at from 2 to 3½ tons per acre. Those who have used Hungarian Grass, speak very highly of its qualities for feeding.

W. O. ATWATER.

**The Onion Fly (*Anthomyia Ceparum*).**

The onion growers are again complaining of serious trouble from a fly, not a new comer, which lays its eggs upon the leaves of the onion. The eggs

Fig. 1.—THE FLY AND PUPA.

thus deposited hatch in a few days, and the larvae or maggots immediately penetrate between the leaves of the growing plant, and begin their work

of feeding and reducing the interior of the onion to a worm-eaten and worthless state. The maggots remain in the onion about two weeks, when they change into the pupa or dormant state, from which

Fig. 2.

THE "WORM."  
The insect is difficult to destroy. The use of salt, ashes, and other substances, strewn upon the soil, seem to do very little good. When a plant is once affected by the maggot, it should be pulled up and burned. The presence of the destroyer is early known by the leaves of the plant turning yellow and falling upon the ground. Onions on new soil are less liable to attacks than those on old onion ground. All affected plants should be destroyed, whether few or many, as it is only by this method that the increase of the insect may be checked.

**A Country House, Costing \$3,500.**

BY S. E. REED, ARCHITECT.

The designs here given, represent a substantial and roomy dwelling, suitable to the wants of well-to-do farmers, and others residing in the country.

Fig. 1.—FRONT ELEVATION OF HOUSE.

**Exterior**—(figs. 1 and 2, see following page). The outlines are irregular and proportionate. Each face has sufficient diversity in projections, and details to give an animated and picturesque appearance. The roofs and gables are treated in a simple manner, to accord with good taste and rural surroundings.... The **Front**, (fig. 1), has a breadth of 35 feet, across which extends a shady veranda, covering the main entrance, and the front parlor window; there is also a pleasant balcony, covering the front sitting room window. The side, (fig. 2), has an extreme depth of 63 feet. A porch protects the entrance to the kitchen from this side. The rear entrance to the main house is on the opposite side of the house.... **Cellar** (fig. 3). Height, 6½ feet. This story includes the entire space below the main house, giving plenty of cellar room for all usual requirements. The outside entrance is from the rear, and a stairway leads to the kitchen.... **First Story** (fig. 4).—Height of ceiling, 10 feet. The principal entrance is from the veranda through double front, and vestibule doors, to the main hall. This hall communicates with each of the principal rooms on this floor of the main house. The parlor doors are double, and directly opposite

to them is a sash door opening to the balcony. At the rear end of the hall is an entry through which the rear stoop is reached. The Parlor and Library adjoin each other through sliding doors, and may be used as one room as occasion may require; each is well lighted, and are sufficiently separated from the living rooms to prevent annoyance in them

Fig. 2.—SIDE ELEVATION OF THE HOUSE.

from the machinery of general house-work. The Sitting-room is a cheerful apartment, with an open fireplace suited to a grate on the hall side, and a large bay window opposite. A front window is arranged with a swinging panel below the sash opening to the floor, and leading to the balcony; opposite to it is a door leading to the dining-room. The Dining-room is octagonally shaped and of good dimensions. It has a large bay window with four full sized sashes extending upward to the ceiling, and containing upper ventilating sashes with stained glass, as can be better seen in elevation, figure 2. This window is a pleasant feature, and with the addition of a double row of brackets, and potted flowers, may be made to serve accepta-

ample light from three of its sides; it has doors leading to the dining-room, pantry, closet, outside porch, and to the private stairs leading to the second story. A pump, sink, and three wash-tubs are set at the sides of the fireplace. The Pantry is thoroughly shelved, and one side dresser-finished with sash doors above and drawers below. The

Cellar Stair-way is situated under the private stairs, and is made to open from the pantry...

#### Second Story (fig. 5).

—Height of ceiling, 9 feet in the main house, and 4 to 8 feet in the rear section. The hall is central, and convenient to the principal chambers, front bed-room, and connects with the rear passage. Each of the principal chambers is large, and has window openings on two of its sides. The rear passage is lighted from a dormer window, and through a sash door this light is transmitted to the main hall. The passage leads to two chambers, a store room, and by the private stairs to the kitchen. All communication between the rear section and the main house in this story, may be

cut off by closing the sash door at the end of the main hall.... **Attic.**—Space for storage, etc., is made under the roof of the main house. It is floored, and has windows in the gables, but otherwise unfinished. The stairs are placed above the main flight, boxed in, and have a door at the foot.

.... **Construction.**—The Foundations are of broken stone and mortar, 1½ foot thick, except where reduced for the stair-way, and are finished to show 2½ feet above the earth grades. For the unexcavated part they extend in the ground below the reach of frost, and have openings in them sufficient to insure ventilation beneath the kitchen floor. The area steps, and coping, and the sills for the cellar windows are of blue stone. The cellar windows are made to swing inside and upwards, and are held open as required by being hooked to the beams above. The Chimneys are of hard brick and mortar, with tops laid in cement. The main frame is of sawed timber thoroughly framed. The inclosing is of double boarding—first with 10-inch sheathing of even thickness, then with 6-inch clear pine clapboards. The roofing is of the best quality of 18-inch pine shingles, and for the principal parts are laid on spruce lath. The valleys, gutters, and leaders are of IX charcoal tin. The inside flooring is of 8-inch spruce, outside of 4½-inch pine. Plastering, hard-finish on two coats of best brown mortar, and seasoned lath, with neat stucco cornices are put in the principal rooms. The principal finish in the gables and verandas, is of timber neatly stop-chamfered, and fitted together. The rafters of the latter are left exposed to sight, with the roof-planking laid face down and beaded, complete for painting. Lattice panels are put under the veranda floors, as shown in fig. 1. The sash and doors are all of "stock sizes," 1½ inch thick, glazed with second quality of sheet glass, and in the two main stories are hung to weights with best cord. All windows in the first story of the main house have panels under them. The doors are of first quality pine, panelled and molded. A force pump is placed at the end of the kitchen sink to throw water into a tank placed under the kitchen roof, and from thence pipes carry water to the sink, and wash tubs.—Painting is two coats of best materials in shades to suit. The following **Estimate** is made at the uniform standard of prices given in previous months, and though differing somewhat from "prices current," will greatly aid in making calculations, especially as to the quantities of materials to use:

225 yards Excavation, at 25c. per yard.....	\$ 56 25

### The Iceland Sheep.

Sheep do not make any exception to the general rule of the great variation of animals under domestication. They are to a large extent creatures of circumstance, and by degrees, sometimes slowly, and at other times rapidly, they change their outward form, and mental characteristics, to suit the conditions under which they are placed. We would not expect that the sheep of the cold and frozen region of Iceland to be the same as those which have adapted themselves to our warmer and richer pastures. In the accompanying engraving a native Iceland sheep is presented, and it will be seen to be different in many respects from those we grow for profit. The accounts of these sheep, given us by travellers, and Icelanders who have moved to this country, are interesting in showing the widely different circumstances under which they live. They are rarely sheltered from the severities of the climate at any season, and little or no systematic provision is made for feeding them in winter. They find shelter as best they can, behind jutting rocks, and in narrow caverns in the mountains. When overtaken by storms, they are often so blinded by the drifting snow, that whole herds in their wild haste to reach some shelter, rush over steep cliffs and precipices, and are killed. When they find themselves surrounded by the storm, or are "lost," as we might say, the frightened sheep turn their heads towards each other and huddle together as closely as possible, so that by the united heat of their bodies, they may be able to out-last the cold of the storm.

One writer says; "Those in the center relieve in turn, those who in the outer part of the circle, are exposed to the greater severity of the blast; thus necessity sharpens the inventions of beasts as well as of men." "The only kindness which these animals receive from their keepers in the winter, is being fed on fish bones or frozen offal, when their natural food is buried too deep even for their ingenuity and patience to reach." It can be seen that these sheep have a hard life to lead; and the care and attention which they get from their owners, is in no sense commensurate with that which they give in return. It would be natural to expect that animals thus exposed to storm and cold, would be protected with a pretty good coat of their own make, and such is the case. It consists of long coarse hair, which extends a number of inches above the dense covering of close wool upon the body. The fleece is thus made up of two quite dis-

tinct materials; and on this account, though it may furnish the best protection for the sheep, is not of first quality for the weaver. The difficulty of separating the two kinds of wool, is a serious objection to the more general keeping of this hardy sheep. They cannot hope to compete with our greatly improved breeds, and if introduced at all, it should be only as a matter of curiosity. This

A SPECIMEN OF NATIVE ICELAND SHEEP.

fact is given as an answer to a direct question; it coming from an Icelandic settlement, the people of which were inclined to import and grow their native sheep. One of the leading peculiarities of the Iceland sheep, is the number of their horns, they usually having more than two, and sometimes eight. The one in the portrait has three, two of them much after the ordinary kind in position and general shape, while the third is back and between

### Peetsi, or the Zebra of the Plains.

The history of the horse, that greatest helper to man among the animals, is lost in antiquity. The breeds and varieties that have been produced, through the many ages that this animal has been bred, are almost endless. Whatever may have been the origin of the horse, and whatever the country

from which he has become spread over almost the entire world, there are certain animals that are his near relatives, and still in the wild or natural state. The horse, the ass, the quagga, and the zebra, are, in fact, so much alike in their important characters that naturalists believe they all came from the same ancestral stock. Buffon, one of the most noted naturalists of his day, went so far as to state that the quagga was a hybrid between the horse and the ass, and therefore of very near kin to the somewhat celebrated light-heeled domestic beast, the mule; a view that naturalists of the present day do not accept. The true zebra is a native of the mountainous regions of South Africa, and differs from the horse in several points; its tail is furnished with long hairs only towards the tip—a point which shows its nearer kinship to the ass

than the horse. The hind legs of the zebra are without warts; the neck is much curved, the mane short and standing erect. The head, neck, body, and legs, are all striped with black bands upon a background of dirty colored white, or white slightly tinged with yellow. It is considerably smaller than the average horse, being about 12 hands in height. Besides the zebra of the mountains (*Asinus Zebra*), there is another found on the plains north

of the Orange River, which is regarded as a distinct species. *Asinus Burchelli* of the naturalists, the Peetsi of the natives, the "Dauw" of the Boers, and the Zebra of the Plains, of the English. This, which is the animal shown in the engraving, has a more comely figure than the zebra proper, and its ears and tail are more like those of the horse, its tail being furnished with hairs much nearer the root than is that of either the zebra or quagga. Especially in its voice, which is a shrill and sharp neigh, with nothing like the bray of the ass, its closer relationship to the horse is shown. Like the

THE "PEETSI" OR ZEBRA OF THE PLAINS.

them, and rising to one side. The supernumerary horns seem to follow no rule either as to numbers, or position upon the skull. When there are more than five horns they are placed in two rows. The use of this extra number of these curious outgrowths from the head is not clear to see; they certainly do not appear to be very ornamental.

zebra and other related animals, it lives in herds, which, when attacked, form a compact circle with their heads towards the center, and their organs of defence, their heels, presented to the enemy; these they are said to use with such effect, and deal out kicks with such force and frequency, that they are able to repel even the quick and ferocious leopard.

### A Kansas Corn House.

We are indebted to W. S. Wadsworth, of Franklin Co., Kansas, for sketches and a description of one of those large corn houses now quite frequently found in the great corn-growing West. Figure 1 shows a side view of the crib, with the end or front in side section. The crib is 113 feet long, by 28

Fig. 1.—SIDE VIEW OF A LARGE KANSAS CORN HOUSE.

feet wide, and has a capacity of many thousand bushels (18,000). The method of storing away corn in a large house like this, is an interesting feature. It is done by horse power, which operates a large belt elevator. On the right of the entrance or floor, of the house, the elevator is seen running from A to B. This is a strong endless belt of leather, which passes over a pulley above and below, and has a series of "buckets" attached to its outer surface. The "buckets" or cups are about two feet apart. The pulley A, is connected with one above the letter D, and this is turned by a tarred rope, which connects it with the large wooden wheel, 5 feet in diameter, at the top of the turn-post, to which the horse is attached. Thus by a proper construction of the pulleys, a sufficiently rapid motion of the elevator-belt is obtained from the ordinary gait of the horse on the "power." The corn is fed to the elevator-cups through a hopper below the floor; shown only in cross section in fig. 1. The wagon is driven in upon the floor, which is provided with a "Dump." A trap-door, 2½ by 3 feet is opened at the rear of the loaded wagon, at the same time the floor is so arranged, that the whole wagon tips back, as shown in side view in figure 2, and the end board of the wagon box being removed, the corn slides into the large hopper below. It is not necessary to have the whole floor arranged to tip, but simply two narrow sills upon which the wheels must be placed. Mr. W.'s floor is so arranged, and this leaves the central portion of the floor stationary, except the trap-

Fig. 2.—END VIEW OF MAIN PART.

door and movable sills. The corn, after it is carried from the hopper at B, to the top of the pulley A, where the cups are inverted, is thrown upon a long smooth horizontal belt, which is run by a cord connecting A, with the belt pulley at F, a short distance below it. This horizontal belt runs the whole length of the storing portion of the house, and just below

the ridge-pole, as may be seen in fig. 1, a portion of the roof being omitted for the purpose of showing it. This belt may be shortened at any time when the rear of the house becomes filled. A simple sliding "shoot" is used at the further end of the belt, for the purpose of turning the corn to one side or the other of the house, thus making the distribution of the grain an easy matter. Figure 3 shows a cross

section of the storing room, and gives an idea of the way the sides of the house are braced, by means of ordinary boards, nailed to the sides of the beams which run from the ground to the roof. "The crib stands on posts cut 26 inches long, and set in

Fig. 3.—CROSS SECTION OF STORE HOUSE.

the ground about one foot, and the ground is so raised that no water will run under the same."

### Among the Farmers.—No. 54.

BY ONE OF THEM.

It is not very long ago that our agricultural papers were printing with quotation marks, and clearly expressed "credit,"—as if the authors should be held responsible for their own Munchausenisms—tales of how Chinese and Egyptian poultryraisers hatched chickens in ovens, or heated rooms, or even in manure heaps. Their readers accepted the tales with grains of allowance, supposing that some truth must lie at the bottom. The times have changed. Now,

#### Artificial Incubation

is established as an economical system, and before long—I hazard the prediction—more eggs will be hatched by kerosene than under hens. Perhaps I live in rather an incubative neighborhood, but in all probability, we are neither more progressive, nor more experimentally inclined, than many others. There is indeed one monster establishment, which I am ashamed to say I have not visited for many months, where the weekly hatch altogether by artificial heat, amounts to several thousands, where the eggs are collected from the surrounding country by wagon loads, and received by express from hundreds of miles away. This, though it may be, or may not be very successful as a business enterprise, is necessarily what common farmer folk can not imitate. It demonstrates, if demonstration be needed, the practicability of egg-hatching artificially. I have been interested in a more difficult problem, namely: Is artificial incubation profitable on a small scale? That I have not yet determined, yet hope what I write may add to the stock of general knowledge on this important question.

I have an incubator for 100 eggs, without any automatic means of either regulating the flame, or

the ventilation. The double water-tank is capable of holding some seven pails of water, and this mass of water changes in temperature quite slowly, so that after a little experience, the lamps may be so regulated, that the fluctuations of temperature are not very great. The most abundant ventilation is provided. This is superfluous in cold weather, but very important in warm, as the products of combustion, when the lamp is turned down very low, are without doubt deleterious to the eggs, or rather the chicks within them. My own days being largely spent away from home, the Incubator was left to the care of a lad of 11 years, who did very well, but could not be expected to take note of all the changes of temperature, and raise or lower the flame accordingly. We have had some fair hatches, and the young birds have proved exceedingly hardy and healthy, quite so much so as any we ever raised. A very small percentage were weakly, and since what may be termed the casualties of the nest, we have had no deaths by disease, and but one or two by accident. A hawk took one, one was chilled in the dewy grass of a cold morning, another was killed by a cross hen, and that is about all. We have used what is called

#### A Hydro-Mother,

which is a brooding box with a water-tank, having a screwed top opening, and which will hold 10 quarts of water. We fill it with boiling water, and the chicks nestle under it, having a few folds of flannel between it and their backs. In cold spring weather, the tank was filled morning and evening, in moderate weather, in the evening only, and as soon as the chicks began to take care of themselves—except on very cold nights—they were left to keep one another warm. When a fresh hatch was added, as a rule, the tank was heated once or twice. This of course in dry spring weather. On cold rainy days, we warmed the tank. I think this system is, on the whole, better than heating by a lamp. The "Mother" we use, will hold about 50 chicks, one or two weeks old. We have adopted the practice of excluding the older ones, by putting wire net of two inch mesh before the door. This forces the big ones to put up with an old fashioned hen coop standing close by, except on very cold nights, when we want them inside for extra warmth for the young chicks, and they are allowed to pass within.

A pair of little wheels were placed under the rear end of the brooding box, and so it is moved about. The chicks thus become accustomed to associate their domicile with no particular locality, which will enable us, as the season progresses, to move them up and associate them with the other fowls. This is the story of our own chicken raising this season. We have kept in the brooder about forty chicks at a time. None have been trodden to death by the hens. None have been killed by taking refuge in the wrong coop. None have been troubled with lice or other parasites of any kind. Gapes has been unknown, and of course they have been thriftier and happier than any similar lot of chickens we have ever raised.

#### Good Luck with Incubators.

I alluded to the fact that some of my neighbors were trying incubators in a small way. They have had better luck than I. Their incubators had self-regulating attachments, and as a consequence there was less watchfulness required to keep the temperature right. They have hatched forty to sixty per cent of the eggs—that is, of the fertile eggs. The story has often been told how plainly

#### The Chick can be Seen in the Egg,

but unless a person makes a study of it and examines egg after egg, time after time, with care and a good strong light, very little idea can be had. Pictures of the appearances would only mislead, for the same egg looks differently as it is turned and as the motions within it are more or less active. Of course all the observations are like watching the movements of vessels in a fog, but yet are quite clear when the observer knows what to look for. It would be worth while for any one to break an egg a day for the first two weeks, for up to nearly that time the examination of the eggs before the lamp will be of use. After that no illumination will give much idea of the continued development,

First, we observe on the second day an obvious cloudiness in some eggs—others that prove fertile show very little if any, perhaps on account of the thickness of the shells. The next day the cloud is denser and more local, the next, the head is seen as a black or dark spot, and about the fifth day it will be observed to move about considerably. A motion due to the fact that the yolk which contains at or near its upper surface the germinal vesicle or seat of life, is caused to float in the albuminous fluid by which it is surrounded, the germ side up, by means of thick masses of albumen, called chalazæ. This floating up of the yolk, and of the cloudy appearance and of the dark spots which indicate the places of the eyes and heart, and more or less of other organs as the time progresses, is of course entirely involuntary, but the motions which may be seen on and after the fifth day are obviously voluntary, and I suppose arise from the fact that the intense light is more or less disagreeable to the little prisoner. In some cases this motion is distressingly active, so that the observer is impelled to lay the egg aside and give the little fellow a rest, for fear of hurting him from over exertion.

#### The Removal of Infertile Eggs

is of course easy, and the thing to do. I found that eggs which had been ten days in the Incubator and were still clear, and when boiled for salad were perfectly good, but of course it would have been just as well to have removed them on the third or fourth day. An infertile egg will remain through the whole period of incubation without essential change, but those in which vitality has once existed, especially if development has once begun and then been destroyed, will soon spoil. So long as eggs remain vital they may be kept fit to eat—at least for many uses. For hatching they should be fresh of course, and the fresher the better.

Eggs should be kept for any purpose in a cool, rather moist place, like an ordinary cellar, and turned once in three or four days. This turning is to prevent the yolk from adhering to the shell. When this occurs the vitality of the egg is lost.

#### Dry Spring Weather.

May drouths are dreadful. Nothing so takes the pluck out of farmers as to see the grass crop burning up in May, or the rye over their broad acres struggling up to get two or three feet high and heading out with ears two inches long. Wheat comes on a little later, and there may be hope for that, and spring grains with plenty of rain may take a start as late as the first of June. With what shall we supplement the lost grass crop?

I am sowing "Golden Millet." I tried it a few years ago and raised a heavy crop, which was well liked by the cattle—rather coarse hay it is true, but if the cattle will eat it as well as they did before, I shall be satisfied. Some of my neighbors are putting in Hungarian Grass. That is an older and better known forage plant, and they know all about it. They have raised "Hungarian" and sold their timothy for years, and are satisfied. The

**New Sorghum, "Early Amber Sugar Cane,"** promises well as a fodder crop, and I have a small patch of that to report upon by and by, but after all when it comes to a main crop—when I must put in something which will surely furnish good and abundant fodder I fall back on corn, Southern White Dent, or Evergreen Sweet. The millets and the sorghums, and the Prickly Comfrey and such things, must stand aside for corn. I suppose I am as old-foggyish as my neighbors who prefer Hungarian to Golden Millet, but old friends and true friends are to be held fast to in such times as these when clover and timothy and even orchard grass "go back on us." This is a season for the French system of *tanking* corn-fodder—"ensilage"—to prove its worth. The experiments, which have been well made, indicate that the value of the process is not much overrated. It is a pity that we can not try this on a small scale, for so many more would thus gradually work into it.

It seems as if a season beginning so dry would prove a wet one by and by, and even if so, the need of fodder crops will be felt, and much can be done after the first of July. Southern cow peas, and all

the millets may be sown after that, and will make a crop with any good superphosphate, or with fine bone-dust and guano. I have had the best luck with that—say fifty pounds of Peruvian guano to a barrel of bone-dust. The war on the west coast of South America makes guano scarce and is likely to cut off our supply. Strangely enough we have no really good substitute for this valuable fertilizer.

#### A Floor for a Cow's Stall.

A floor so constructed as to allow of the quick removal of all liquid manure, and thus be kept

Fig. 1.—A PORTION OF THE FLOOR.

comparatively clean, is shown in the accompanying engravings. The sketches and description are from "C. A. N.," Rockingham Co., N. H., who has had a floor of this kind in use for some time, and is highly satisfied with it. Figure 1 represents a part

Fig. 2.—SINGLE SLAT.

of the stable floor, the front portion, *D*, for the manger and the fore-legs of the animals, is solid flooring. The rear portion is made of deep, but narrow slats, *F*, which are wedge-shaped, being narrow below and placed one inch apart. The slats, one of which is shown in figure 2, are 3 inches deep, 1½ inch wide out top and ¾ inch on the bottom. The floor complete is shown in figure 3. The slats rest on cross-timbers, and are far enough from the floor below to permit the use of a hoe in removing the manure, and also to rake under litter of any kind to absorb the liquid manure. The floor should

Fig. 3.—THE FLOOR IN USE.

be so long that there may be no danger of the cow stepping off at the rear. "The slats should be of

white oak or some hard-wood that will not break or wear out quickly. Those who have used this plan of floor for the stable like it very much; it gives the cows a chance to lie down with some comfort."

#### A Log Raiser.

It is the thoughtful man who avails himself of any contrivance by means of which a heavy load can be moved without the direct application of main strength. This is what is called *advantage* in mechanics; and it can be obtained by the use of any one of the six mechanical powers, viz., the lever, wheel and axle, pulley, inclined plane, wedge, and screw; or a combination of two or more of these working together. To this end, the gaining of advantage, all machines are made. Mr. Peter Werner, Dubuque Co., Iowa, sends a sketch and description of a device for raising logs, which is shown in the accompanying engraving. The standard consists of two hard-wood planks 2 by 6 and 7 feet long; cleats two inches thick are inserted between them at the ends, and well fastened by bolts. A support 2 by 2 inches of sufficient length, and fastened with a bolt, holds the standard in position. A lever 4 feet long, with a hook, passes between the two planks of the standard. The latter has two rows of holes 4 inches apart and 3 inches apart

A DEVICE FOR RAISING LOGS.

in the rows. Two stout pins are necessary to hold the lever, which latter is provided with notches to fit the pins. In working the machine the pins are alternately moved up a hole at a time. "In this manner, a man can raise a log 3 feet in diameter on to the wagon without other help." There is certainly an *advantage* to be gained in using such devices if the most is to be made out of a limited amount of muscle or power of any kind. Of course it takes longer, but it is easier, and in that is the gain.

**Hungarian Grass.**—A quick growing plant is required for the production of a second crop upon the early rye or other stubble, and this is well supplied in the Hungarian Grass. If the season is warm and the moisture sufficient, with a rich soil, a large crop of this valuable fodder may be produced in from six to eight weeks. About one bushel of seed is required per acre, to be sown broadcast and slightly harrowed in. From the rapidity of its growth, the Hungarian Grass may be safely sown as late as July; but the best results may be expected when sown as early as June. Sown at intervals of a week or so it will give a succession of excellent succulent green fodder, and that when other green food is often scarce. The plant, when allowed to ripen fully, has a head bearing a multitude of hard, sharp bristles or awns, which are irritating to the stomach, especially those of horses which have fed abundantly upon it. Trouble from these can be avoided by cutting the crop so soon as the head is formed, and at the same time a better fodder in all other respects is obtained. Its excellence as a soiling crop is only equalled by its value for fodder when cured as hay. A few acres of Hungarian Grass on any farm is a good index of thoughtful and profitable farming.

## A Cheap and Convenient Poultry House.

Poultry Houses may be expensive buildings—or suitable accommodations that answer the purpose equally well may be very cheaply made. The essential requisites are a warm, dry, well-lighted and ventilated shelter, that will ensure comfort in winter, with convenient arrangements for roosts, feeding space, and nest boxes. In winter, light and warmth are of the first importance. Fowls will not lay when confined in cold, wet, and dark apartments. Windows facing the south or southeast, large enough to admit the sun freely, should be provided,

Fig. 3.—FRONT VIEW OF POULTRY HOUSE.

and made to slide so that a free circulation of air can be secured in summer. The accompanying plan or a poultry house will be found convenient, when two varieties of fowls are kept; yards being made in front of each compartment for an out-door range, when it is necessary to keep them in confinement. If but a single variety is kept, the hall and compartment at one end will answer the purpose, and the door, A, fig. 1, opening at the side, may be placed at the end. The ground plan, shown in fig. 1, is 10 by 29 feet; apartments for fowls 10 by 12 feet; A, outside door; B, hall, to provide for storing feed, giving access to the nests without entering the apartments in which the fowls live. Slatted gates, 6½ feet high, are placed at C; the space above the gates, and above the nest boxes, should be slatted to allow a free circulation of air. Large windows are in the side at D, D'; E, nest boxes; F, roosts. The back nests are 4 feet high, front nests 2 feet; with large Asiatic fowls the roosts should be made nearer the floor. Figure 2 is a section through the middle of the house—from O to P, in fig. 1. The slats in front of the nest boxes are marked H; other letters as in fig. 1. The front elevation, 9 ft. high, is shown in fig. 3. The doors, G, G', for fowls, are near the main door, A, and within reach from the hall, so that they can be readily closed without going into the fowl apartment. An opening may be made over the main door, A, for the purposes of ventilation, with a sliding shutter that may be partly or entirely closed from the alley. The nest boxes may be 1 foot wide and 16 inches high. For convenience in cleaning, the nest boxes may be made in sections, so that they can be readily taken apart. The architectural

Fig. 1.—GROUND PLAN OF THE HOUSE.

finish of the exterior is a matter of taste, and may conform to that of the surrounding buildings, or, where cheapness is an object, something like fig. 4 or 5 may answer the purpose. Poultry houses are frequently made as a lean-to against other buildings, but all things considered, it is best to have them stand apart, and by themselves. They are

not desirable near the horse stable, as vermin are liable to get on the horses unless extreme care is constantly exercised in their extermination.

## The Use of Hay Tedders.

Since the introduction of the mowing machine there has been no implement put into the hands of the farmer of more importance than the Hay Tedder. At the present time, tedders are so perfect in their mechanism, and so easy in their action, that they may be ranked among the necessary labor and time-saving machines of the farm. The tedder is of more importance now than in the days when the grass was cut with the scythe, because the mowing machine leaves the grass evenly and compactly spread—like a blanket—over the surface of the meadow, so that while the upperside becomes parched and brittle, the lower portion remains wet and green. The swathes of the scythe mower were shaken out by a hand fork, and the grass left in a position for the air to penetrate the mass to dry

it. Now, the tedder follows the mower and tosses the closely laid grass into all sorts of "criss-cross" shapes, and the very best conditions of rapid and even curing are thus provided. By its use the hay may be in many cases so rapidly made that the green grass cut in the morning is well cured, and may be housed, hay at evening. The value of hay depends so largely upon the way in which it is cured, that when the importance of the tedder is considered we must look beyond the time and labor saved, and note that the quality of the hay is much improved by its judicious use. In view of the ex-

Fig. 2.—VERTICAL SECTION THROUGH THE HOUSE.

perience which the American farmers have thus far had with hay tedders, it is clear that they are not only economical machines, but a growing necessity.

## Feeding Waste Products—Starch Feed; Grains, Etc.

Various manufactures produce refuse which has more or less value, and it not rarely happens that the success of a process may depend upon the proper disposal of this refuse. Farmers are interested in some of these articles. The English farmer finds it profitable to send to this country for the refuse of our manufacturers of Linseed Oil, in the shape of Oil Cake. The refuse of breweries has

long been used under the name of "grains," as have bran and other refuse of the flouring mills. The introduction of the manufacture of starch from corn, brought another material, "starch waste," to the notice of farmers, and still more recently, the production of glucose, or grape sugar, from corn, has placed still another refuse product on the market as Sugar Waste, Glucose Waste, or

Sugar Meal. Some of these refuse products, like oil cake, can be transported a long distance, and be kept without change, while others are readily perishable, and can only be utilized as food for stock by farmers who live near the factories. The number of inquiries concerning the feeding values of these waste products, show that farmers are inter-

ested in the matter; these, as well as inquiries as to the feeding value of other grains, as compared with corn, were referred to Prof. Atwater; we bring his several replies together in the present article.

## "Corn Feed." "Starch Feed,"

waste from the manufacture of starch and glucose from corn. No analyses of waste from glucose manufacture are, so far as we know, accessible. Below are analyses of "Starch Waste," or "Corn

Fig. 4.—END VIEW.

Starch Feed" from the Glen Cove Starch Manufactory, Long Island. No. 1, analyzed by Prof. Atwater, "as taken from the factory," weighs from 75 to 85 lbs. per bushel, averaging 80 lbs., and costs 23 cts. per 100 lbs. It is fed to milk cows, about one peck at a feed, being mixed with corn

meal, bran, and sometimes roots. No. 2, analyzed by Prof. Johnson, is described as "sold in New Haven, Conn., at 20 cts. per bushel....a moist, slumpy, mass, with a sourish smell."

	No. 1.	No. 2.
Water.....	72.19 per cent.	62.27 per cent.
Ash.....	.12	.27
Albuminoids.....	3.56	5.67
Woody fibre.....	3.36	1.58
Other Carbohydrates.....	18.73	28.90
Fats.....	1.99	1.31

No. 1 is calculated to contain, in digestible form: Albuminoids, 3.2 per cent; Carbohydrates, 19.3 per cent; Fats, 1.8 per cent. Reckoning these digestible

nutrients at 4½ cts. per lb. for albuminoids and fats, and ⅙ cts. per lb. for carbohydrates, the valuation would be 39 cts. per 100 lbs. Doubtless the glucose waste is very similar to the starch waste.

## Corn Meal and Grains—Their Feeding Values.

In the *American Agriculturist* for Jan., 1879, p. 10, Dec., 1879, p. 497, and Jan., 1880, p. 9, are analyses and valuations of feeding-stuffs with explanations. The following figures, from these and other sources, refer to American products. They represent, not the total percentages of nutritious materials, but the amounts that are calculated from composition and results of feeding trials, to be actually digestible, and hence nutritious:

FEEDING STUFFS.	Digestible Nutrients.				Nutritive Ratio.	Valuation. Not as per 100 pounds.
	Albu- min- oids.	Carbo- hy- drates.	Fats.	as 1:		
Corn, N. E. yellow, 8-rowed..	8.4	66.8	2.3	8.8	1.04	
Corn, Western, yellow.....	7.5	67.9	2.5	9.9	0.97	
Corn, Southern, white.....	8.2	67.6	2.4	9.1	1.04	
Corn, sweet.....	9.6	16.8	5.9	8.0	1.19	
Oats, No. 1, white.....	8.7	43.3	4.0	6.2	0.94	
Barley-feed.....	10.1	57.1	2.1	6.2	1.05	
Rice-feed.....	7.8	49.1	1.4	7.3	0.82	
Wheat-bran, (shorts).....	10.0	48.5	3.1	5.6	1.01	
Middlings.....	8.9	54.8	2.6	6.9	1.00	
Eye-bran.....	12.2	46.2	3.6	4.5	1.09	
Starch-waste (from corn)...	8.2	19.3	1.3	7.4	0.39	
Malt-sprouts.....	26.3	43.7	0.9	2.2	1.33	
Palm-nut meal.....	12.9	56.8	14.0	7.2	1.67	
Cotton-seed meal.....	33.2	17.6	16.2	1.8	2.80	
Linseed-cake.....	27.6	27.0	10.4	2.0	1.89	

EASTERN vs. WESTERN CORN.—The analysis of "Western Yellow" Corn represents sample as brought in bulk from the West. Western Corn, well cured and housed, is fully equal to Eastern, but the field-cured corn, as it actually comes to the Eastern markets, seems to be somewhat inferior to our home-grown, as the figures above imply. Those who wish to study into the composition of American Corn, and other Feeding-stuffs, will find a valuable Compilation of Analyses of these foods, by Dr. E. H. Jenkins, in the Report of the Connecticut Agricultural Experiment Station for 1879.

London Purple vs. Paris Green.—Both of these substances are deadly poisons, and equally effective in killing the Potato Beetle. The "Purple" has some advantage over the "Green" in its greater cheapness, it being a secondary product in the making of aniline dyes. Cheapness obviates the

temptation to adulterate it, as has been done with Paris Green. The Purple is more finely pulverized and can be more thoroughly distributed either in the dry or wet way, and its color is more striking than the "Green," an important characteristic in any poison, making it more conspicuous to the eye.

### About Training Animals.

"The Ox knoweth his owner, and the Ass his master's crib," was the expression used 2,640 years ago, by one of the grandest writers of that period, when he wished to express the stupidity of a people who could not or would not think or "consider." The form of expression and joining him with the ass, show the low estimate placed upon the intelligence of the ox in those days, and there has been little change in this respect down to our

over the prostrate one; and they climbed and stood upon boxes scarcely larger than a harrel; one would stretch himself out with his fore and hind feet upon two separate boxes, and the other crouched down and passed hack and forth under his mate as often as directed to do so, and then changed places and repeated the performance; they walked up and down stairs, also came up in opposite directions, saluting (we suppose) as they passed. The boys cheered the most when one of them mounted the platform at the head of half a dozen steps, and reaching up his head pulled a string with his mouth that fired a pistol on the top of a pole above. (But this was a trick—the boys at a distance probably did not see that there was a small toothsome carrot on the end of the string.) The older people joined most in the cheering when these oxen deliberately, and with a good deal of ingenu-

TRAINED OXEN ENJOYING THE SEE-SAW OR "TEETER-BOARD."

own times, despite the wonderful improvements made in the physical form of some bovine breeds. We attribute to horses a knowledge almost human, in the feats they are taught to perform, and we all have seen or heard of the "learned pig" even. But the most that is expected or sought for in the ox is to understand "Haw," "Gee," "G'long," and "Whoa," and the failure to do so brings the inevitable blow from the goad. Thanks to a Massachusetts farmer, and to the enterprise of the noted showman, this low estimate of our patient, faithful servant is likely to be greatly modified. The tens of thousands of boys, and men too, who visit Barnum's "Greatest Show on Earth," as he is pleased to call it, will carry home one new idea at least, if they profit as much as we did, by dropping in specially to see the "trained steers," as that came directly in the line of our profession. They will learn that patience, kindness, firmness, with a reasonable amount of mental ability themselves, and using it, will bring the ox up to almost as high a degree of intelligent action and performance as has ever been exhibited by any other domestic animal, whether horse or pig, and we had almost said dog, though if half the stories told of dogs be half true, we must allow them to be a good deal human. One useful lesson we doubt inculcate is, that, as patient as is the ox, he doubtless feels, more than we are apt to think of, the cruel blows that are ever falling upon him from the first hour of being yoked until led to the slaughter-house, and not even there allowed the most kindly mode of sacrifice—as witness the clubbing, the torture of being swung up by one leg, encircled with a chain, etc. A second lesson is, that by proper treatment he may be trained to be even a much more serviceable friend and servant than he now is. Our own artist has illustrated, a single feat we saw performed by a pair of young steers—grade Alderneys, or perhaps a cross between Alderneys and Ayrshires, said to be twins, rather under medium size, of dark chocolate dun color, shading into black, with flecks and patches of white—about three years old, and raised, we believe, by Henry N. Taft, of Worcester Co., Mass. Well, these trained steers or oxen marched to the sound of music, danced to it a good deal better than the writer could; they, at word of command, or by motion of a whip (not hit by it) changed positions, lay down in different postures and places; knelt and walked about on their knees; they gambolled with each other in various ways, just as signaled to do by word or a wave of the hand; they each lay down, and the other walked

over the prostrate one; and they climbed and stood upon boxes scarcely larger than a harrel; one would stretch himself out with his fore and hind feet upon two separate boxes, and the other crouched down and passed hack and forth under his mate as often as directed to do so, and then changed places and repeated the performance; they walked up and down stairs, also came up in opposite directions, saluting (we suppose) as they passed. The boys cheered the most when one of them mounted the platform at the head of half a dozen steps, and reaching up his head pulled a string with his mouth that fired a pistol on the top of a pole above. (But this was a trick—the boys at a distance probably did not see that there was a small toothsome carrot on the end of the string.) The older people joined most in the cheering when these oxen deliberately, and with a good deal of ingenu-

ity, managed to get on to the opposite ends of a long plank placed across a center stand two or more feet high as a fulcrum, and then changed their center of gravity and see-sawed as prettily as any two boys or girls do when they call out, "now we go up, up, up, and now we go down, down, downie." And still more, one of them took position over the center, and by throwing his weight first upon his hind and

#### How to Do It.

The writer has had a certain success in training animals, which leads him not only to appreciate good results, but to know by what means they were brought about. When dogs are trained under the lash, they may do very well, but it is crouching, with the tail between the legs, with a certain uncertainty, as if they did not know for sure whether the dreaded lash might not be their reward even for well doing. This is pitiable, and is not the case with Mr. Barnum's cattle. They know that the whip is in reserve—and that is right. They have enough of what we may say is "human" in them to need both the reward of well doing, and the dread of the consequences of inattention and laziness. These are the "hesetting sins" of oxen, and in fact of animals generally—as well brute as human. Now and then we have a horse, a dog, an ox, not unfrequently a boy, nervous, wide-awake, quick, thoughtful, prompt, easy to teach, that is, quick to learn, and with a good memory. Such are pleasant pupils, and do their teachers credit, but it is no reason why the stupid or less bright ones should not also be trained. Here is where the use of the whip comes in, not to produce fear of the consequence of honestly made blunders, if we may use the expression, but to keep the faculties active, and the wide-awake condition the prevailing one—not a punishment, but a spur. The observations apply equally to horses, dogs, cattle, and children, but of course each of these has its peculiar nature and tendencies which must be rationally considered, and must guide our

training; with oxen which are slow in their motions, and deliberate in their thought and perceptions, the quality of patience and kindness is especially necessary in training. It is easy to make any animal wild and scary, and so spoil the work of hours of patient labor, and cause a lack of that confidence in the trainer which is absolutely essential to success. When provoked by stupidity or wilful obstinacy, the trainer is very apt to get angry. It is the worst thing he can do, and if he can't help it, the thing for him to do—the *only* thing for any teacher to do—is to lay down his whip or rod and go away by himself and cool off; stir up in his own heart a sympathy for the brutes or for the boys.

We do not mean that in training animals a man may after a while go back, when cooled off—and then punish—that is well enough in the case of boys, for we "humans" have better memories and reasoning powers than brutes, and understand that punishment may be delayed and still be just, while with animals the punishment must always follow the offense quickly, promptly, kindly, coolly, *coldly*, as if a law of nature had been broken. If an ox runs into the thorn-hush, the thorns prick, they scratch his hide, they enter his flesh, they *hurt*—not after a while, but then and there, without consideration or pity. The punishment is exactly measured to the offense. We have an advantage over this thorn-hush system of training in that we may use persuasive measures—*rewards* as well as punishment—carrots and sugar as a reward for well doing. When the cattle in the show fired a pistol, they did it by nibbling at a carrot. (We suggest to the great Showman that a duel between the oxen, with clowns for seconds, a mule for referee, and the carrots labelled "satisfaction," would be an appropriate satire, which would be appreciated by the people and satisfactory to the cattle, if the carrots be fresh.)

**A Garden Brush.**—Mr. L. Prentice, Leavenworth Co., Kansas, sends a sketch and description of a Garden Brush which he has "used with great satisfaction for putting in small seeds. It consists of three poles about three inches in diameter, two of which are arranged as cross bars pinned together near each end, but about eight inches apart; and the third one, serving as a tongue, passes under the front bar and over the rear one, and is pinned

Fig. 1.—CONSTRUCTION OF THE BRUSH.

or bolted to both. The front bar has several upright pins on which the brush is hung by forks in the brush, and passing under the rear pole is held at an angle of about 45 degrees, bringing the small ends of the brush into wear until worn too short, when they are easily replaced." The construction of this garden brush, which is so handy for smooth-

Fig. 2.—THE BRUSH COMPLETE.

ing over the ground and covering small seeds down in rows, is shown in figure 1, and in figure 2 it is complete and ready for use in the garden.

## Keeping One Cow.

[SECOND PRIZE ESSAY.]

[The judges who patiently went through the task of reading over 70 essays of various lengths, inform us that there were many of these that in some one particular were superior to all others, but that in awarding the prizes they were governed solely by the conditions of the offer. We here give the essay to which the second prize was awarded. It was signed "Doctor," and was found to be by W. L. Battles, Gerard, Pa. The prize essays, together with several of the most desirable of the others, will soon appear in a pamphlet or book form.—Eds.]

Instead of writing on how a cow might be kept, I propose simply to tell just how we manage our cow, what we feed her, how we procure that food; in fact, everything relating to her care, so that any one can go and do likewise.

"Spot," we call her, for she has a beautiful white spot in her forehead, is not a Jersey, for we can not afford to buy one at the prices at which they are held with us; nor is she a thorough-bred of any kind; yet she is a good cow, of medium size, fills a twelve-quart pail each night and morning, when her milk is in full flow, that raises a thick coat of rich cream, which, after being churned, furnishes all the butter needed for a family of six, and some to spare. Our place is small, only two acres, and a portion of this is covered by the dwelling, barn, poultry-house, etc. The fruit garden occupies about one-fourth of an acre, and from this portion nothing is grown to furnish food for "Spot." Adjoining the barn there is

### Half an Acre in Grass,

or mostly clover; fine manure is liberally spread over this each spring and fall, and every spring a quart of clover seed is sown, so as fast as the old plants die out, young ones take their place. A bushel of land plaster is sown on this when the grass begins to start in the spring. This plot produces a very heavy growth of grass and clover, enabling us to cut it three times each season; about the first of June, August, and October. A coat of fine manure is always spread over the ground immediately after each mowing. The grass is mostly cured, and makes fine hay for winter feeding. Occasionally a small portion of the crop is used green for soiling. Besides the land occupied by buildings, fruit garden, and clover plot, there remains about one acre, which we call the garden. Here are grown all the vegetables for the family's use, besides some to sell. About one-fourth of it is planted to Early Rose potatoes, and as soon as these are sufficiently ripe for use or market, they are dug, and sweet corn, in drills, for fodder, is sown upon the land. Another fourth of an acre is planted to sugar-beets; the ground being very rich, the yield is always large; this season (1879), although very dry, I harvested 178 bushels. Our cow is very fond of the beets, and I think there is nothing better to keep up a flow of milk, and they give it no bad flavor, as do turnips. An additional fourth of an acre is planted to sweet, or evergreen, corn; as fast as the corn is picked for use or market, the green stalks are cut up, run through the cutting-box, and every particle of them consumed. As soon as the corn is all harvested, the ground it occupied is thoroughly fitted and manured, and then sown to winter rye, to be used for soiling the next spring, after which the ground is again prepared for corn. The remaining fourth acre is devoted to early peas, beans, cabbages, and other garden vegetables; as soon as one crop is off, the ground is prepared, and something else is almost always planted or sown; consequently, on the most of this acre, two crops are produced each season, except where sugar-beets are grown, or late cabbages, which require the whole season to mature. With the clover on the half acre, and the forage crops and roots on the acre, we have not only had sufficient food for the cow the entire season, but have also kept our family horse, with the exception of one load of oat straw purchased for three dollars, to mix in with the fodder corn; this is hard to cure sufficiently to keep bright and sweet through the winter, but by mixing a layer of corn-

fodder, and a layer of straw, it all comes out nice and bright. Besides keeping both horse and cow, we have marketed from this little farm, in berries, vegetables, butter, eggs, poultry, and one fat hog weighing, dressed, over 300 lbs., \$468 dollars worth of the above produce, keeping enough for our own use, and salting down one barrel of pork.

The barn is 25 by 30 feet, with the stable on the south side. The stall for "Spot" is five feet wide, and the floor on which she stands is five feet long, with a manger two feet wide in front, one and a half foot high next to the cow, and three feet next to the barn floor. She is fastened with a wide strap around her neck, attached to a chain eighteen inches long, which is fastened to a staple driven into a post at a corner of the stall adjoining the manger; this gives her room to turn her head so as to lick any portion of her body. The floor is made of two-inch plank, battened on the under side with thin boards, raised from the ground ten inches in rear and one foot in front; all the droppings and urine fall into the four-foot alley behind. This alley has a clay floor beaten perfectly solid and level. Next to the stable door is a large bin, 10 by 7 feet, for storing road-dust or muck; at the other end of the stable is another bin, 10 by 11 feet, for storing leaves for bedding. My great object is not only to make "Spot" comfortable, and have her stable free from all bad odors, but to save all the manure, both liquid and solid. I find the

### Best Absorbent to be Dried Muck,

pulverized, or road-dust from clayey roads. As it is easier to procure the latter, I generally make use of that, and always keep from two to three inches of it in the alley; this effectually absorbs all the liquid portions and all offensive odors. Twice each day this is thrown out through a window closed by a sliding shutter in the rear of the stall, under a shed, where it remains until wanted for use. In the fall I go to the woods and procure a sufficient quantity of leaves to last until spring; a liberal use of these not only makes a nice, soft, clean bed, but largely increases the quantity of manure. The stable opens into a small yard, across one corner of which runs a small brook. Each morning the cow is permitted to go out and drink; if the weather is pleasant, she is allowed to remain out an hour for exercise. She is let out the same at night, after sunset in warm weather, so that she will not be annoyed by flies. The barn is well battened, and is warm in winter; it is well ventilated by two windows, but these, in summer, are darkened by blinds, with wide slats to keep out the flies. Each morning, while "Spot" is eating her breakfast, she is well curried with a curry comb or card, and if any filth is observed on her bag or teats (which is very seldom), it is carefully washed off, if in winter, with warm water. She is

### Always Treated Pleasantly, Never Scolded,

nor whipped; consequently she never kicks over the pail, or holds up her milk. She is fed in winter with a peek of sugar-beets cut up, both morning, noon, and night; also a bushel of cut feed, either corn-stalks or clover hay, wet with a pailful of hot water, with two quarts of "sugar meal" or bran, thoroughly mixed together, with a little salt sprinkled over it. I generally use what is known here as "sugar meal" to mix with her feed; it is corn meal from the factory after the sugar or glucose has been extracted; it costs from 10c. to 12½c. per bushel, and I prefer it to bran, and "Spot" likes it very much. We consider her a machine for converting the food we give her into milk, and the more we can get her to eat and digest, the more milk is obtained, and the greater the profit. It is a good plan to change the food occasionally, substituting carrots for beets, clover hay for corn fodder, for brutes, like mankind, are fond of a variety.

There are root-cutters that can be procured for cutting up roots, but I have always used a common spade, ground sharp, and an empty flour barrel to hold the beets. It takes but a few minutes to cut up a mess of beets in that way. With one bin full of road-dust, and the other full with leaves, a winter's supply of litter is secured, and it is surprising what a pile of manure we have in the spring. Another valuable source of manure is the pig-sty,

with plenty of leaves for a warm bed, and sufficient road-dust to absorb all the liquids, it is astonishing how clean our pigs are, and the sty is free from all bad odors; the big potatoes, and mammoth beets, show the richness of the pig-pen fertilizer. I think our fifty hens pay for all their food with the droppings the poultry-house furnishes. The roosts are over a slanting platform, which is kept covered with road-dust both summer and winter, the droppings fall on this floor, and roll down into a large box twelve feet long, three feet wide, and three feet deep. The dust the chickens work down with the droppings is sufficient to absorb all the ammonia and preserve all the fertilizing qualities of this most valuable guano. A large box of road-dust is always kept in the water-closet, a liberal use of which furnishes a quantity of most valuable fertilizer, besides freeing the closets from all noxious smells. The wash water and slops from the kitchen are utilized by being thrown on a pile of sods and other rubbish, which are forked over, and as soon as decayed, carted to the manure pile. From so many sources we are enabled to give our small farm a

### Most Liberal Supply of Manure

each spring and fall, so that even with the double cropping most of it gets, it continues to improve, and yields more bountifully each succeeding season. For sugar beets, the ground is first manured heavily, plowed deep, and thoroughly pulverized with the cultivator, then marked out in rows with a garden plow, two feet apart. Manure from the poultry-house is scattered in each furrow, which should be lightly covered with soil, so the seed will not come in contact with it; drop the seeds about six inches apart, covering lightly with the garden rake. When the leaves are about four inches long, thin out to one plant in a place, and fill any vacancies with the plants pulled out. Hoe them thoroughly, destroying all weeds, which can easily be done by cultivating each time before hoeing, with a narrow cultivator. Keep the ground mellow, and cultivate three or four times, after which they will take care of themselves and soon cover the ground. With ground in good condition, and a fair season, 600 to 800 bushels per acre can be easily produced. Let them grow until frost comes, when they should be dug with a garden fork, the tops cut off, and stored for winter. Those to be used before the first of March, are stored in the cellar, the others are buried in a long pit, digging out a shallow place, piling up the roots about three feet high, and three feet wide, covering well with straw and sufficient soil to keep them from freezing, putting in a drain tile about every four feet in the top of the pile, with one end to project a little through the covering, for ventilation. If the weather becomes very cold, lay a turf over the tile, and remove when pleasant. I grow carrots after the same plan, and store in like manner. I prefer beets, as they are so much larger, it is less trouble to gather and take care of them, and the crop is generally larger, still I always grow some carrots for a change. I plant sweet corn in drills, always put some fertilizer along the furrow, dropping the kernels about eight inches apart, with the rows three feet wide, I commence planting soon after May first, and continue at intervals until about July 1st, so I can have a fresh supply for use, and market, all the season. The sweet corn being grown on the plot sown to winter rye, for soiling, enables us to eat some portions of it twice, before the ground is needed for corn. When sowing corn for fodder, which is done as soon as we commence digging the early potatoes, I sow it in drills two feet apart, and drop the kernels about one inch apart in the drills, manure from the pigsty is first dropped in the furrow, and covered with soil at least two inches deep, or the corn will not come up. This fertilizer is so strong, if properly used it causes a most extraordinary growth of stalks. While the corn is small, cultivate it two or three times with a narrow cultivator, when it will take care of itself, and there will be a surprising growth of stalks; I have them often six feet high. Just before time for frosts, cut it with a scythe, and set up in small bunches bound around the top, and leave to cure until cold weather. When it is to be put in the mow, spread

alternately a layer of stalks, and a layer of straw, and it will keep bright and sweet until wanted.

#### The Rye for Spring Soiling,

is sown when the sweet corn is picked, and stalks removed, in drills about ten inches apart. Fine manure is spread on the ground after plowing, and thoroughly mixed with the surface soil, and one or two hoeings being given to keep the ground mellow, and to destroy any weeds that may make their appearance. By May 1st, the early sown rye will cover the ground with a dense growth, at least four feet high, furnishing a large quantity of most nutritious green food. On those portions of the plot where the latest corn is to be planted, two or three cuttings are made; this makes most excellent food for the cow, and the quantity grown on this fourth of an acre will surprise any one who has never tried it. There is quite a plot of early peas, and as soon as the last picking occurs, while the vines are green, they are pulled and fed to "Spot," who relishes them very much. Turnips, or corn, is at once sown on the ground where the peas were.

When our early cabbages are taken up, all the leaves, and much of the stalks, are turned into milk by taking them to the cow's manger, and the ground at once platted, or sown, to something that will make more food. The beet, carrot, and turnip tops, and late cabbage leaves, make quite a quantity of feed late in the fall, if care is taken in saving and preserving them. Possibly there may be some better forage crop than "evergreen," or sugar corn; I think another fall I will try the Minnesota Amber Sugar Cane, in a small way. I tried Pearl Millet, in one row, this season; it tillered, or spread wonderfully, but did not do so well as the corn, as the stalks were small, and the millet makes such a feeble growth, at first, it requires the whole season to make as much fodder as I get from corn sowed the fourth of July. I generally manage to have the cow come in about the first of September; by that means, the six weeks she is allowed to go dry, occurs during the very warmest portion of the summer, during July and August, when, with the facilities the person possesses who keeps but one cow, it is difficult to make good butter; it is also the season when butter most generally sells the lowest.

The calf is taught to drink after it is a week or ten days old, and fed on a porridge made from skim milk and wheat middlings, or shorts; by the time it is six weeks or two months old it will be well fattened, and can be sold to the butcher for veal, at a good price, for at that time of the season veal is scarce and in demand. The cow being in full flow of milk all winter, when butter is most always high, will pay a good profit for her feed and care. A couple of weeks previous to the time the calf should be born, I make a box stall on the barn floor, and permit the cow to run loose in it until the calf is taken away to learn to drink. During this time she should have a good bed of leaves, and the stall cleaned each night and morning. So far at such times I have experienced no difficulty, or trouble; should any occur, it is better to apply to an experienced person, than to try and doctor her yourself. After the calf is born, I feed the cow on warm slops a day or two, permitting the calf to suck until the swelling has gone from her bag, and it has assumed its natural condition, then, as before stated, teach it to drink, which can easily be done, by inserting the finger in its mouth, and putting its head in the dish, cautiously withdrawing the finger, a few times, and in a short time you will have no difficulty, as it will help itself.

In conclusion, I can say I have tried to state just how our cow is managed and kept. I presume there can be improvements made on our system. I shall be glad to take advantage of the experience of others, at any and all times. No record is kept of the milk obtained, nor the butter made. We know we have always plenty for the family's use, and considerable to spare. Bread and milk furnish the children half their food a portion of the time; pure milk and plenty of fresh fruits, in abundance, we consider to be one of the principal reasons why our family is so healthy, and we have so few doctor's bills to pay.

From our acre and a half, all the food has been

grown for both cow and horse, except the \$3 expended for straw. The "sugar meal" given the cow has not cost over \$5 during the past year; it is safe to say that one half, and probably more, of the clover, corn fodder, green rye, etc., has been fed to the horse, consequently the keeping of the cow can all be credited to the small area of

#### About Three-fourths of an Acre

of land, in addition to an outlay of not exceeding \$7 for meal, bran, and straw. This land, about one half of it, has also produced, in addition, full crops for the use of the family, or market, while the sour milk, and buttermilk have largely assisted in making 600 lbs. of pork. The calf, at less than two months of age, was sold for \$8, which more than paid for the extra feed bought for the cow. The family that has never kept a cow can hardly realize the satisfaction and benefits derived from such a source. Children, whose appetites are often capricious, will almost always relish a cup of cool milk. Cream, for our coffee at breakfast, is much enjoyed by all, but realized by few, and what can be more delicious than a nice dish of strawberries smothered in rich yellow cream. When we consider the small expense, the little trouble and care, contrasted with the great benefits derived, it seems surprising that any family will deprive themselves of so great a boon as that of keeping a cow. "DOCTOR."

#### Novelties are not always New.

Implements and devices of various kinds are from time to time brought out and fully explained as new, when the facts are frequently far otherwise. An illustration of this came to our notice a short time ago, in looking over an old work on agriculture, entitled, "The English Improver Improved, or the Survey of Husbandry Surveyed" (1652). On page 203 of this ancient work, a number of plows are figured, among which is, "The Double Plough, ploughing two furrows at one time." It is not to be expected that 228 years of the most progressive time in the world's history has brought no change in the construction of double plows; but nevertheless the fact of their antiquity remains the same. The directions for the making of the old double plow are very full, and as a matter of historical interest, we give some of the points, together with an exact reproduction of the plow itself. "The double plough shall be as plain as may be, it shall consist of one long beam of an ordinary length, and another short one, little above half the length of the other. . . . I proceed to the making of the hinder-most plough, which must be made in all its members and branches like the other, except the beam cut off three inches before the Coulter-hole. . . . The handles upon the last plough you must set to the

Fig. 1.—THE DOUBLE PLOW OF THE 17TH CENTURY.

placing of it in his place, which I discover thus, the first plough standing in its working posture, the other plough with the handles to it, to be affixed on the nearer side, or left-hand, one furrow-breadth wider than the other, just in the same posture, both for depth and breadth as the other doth, and so held off from the first plough-beam, by a lining or filling of wood, just that substance as may continue it firm and fast. . . . All which may be so keyed and cramped up, that it may be as one solid beam, and so move as the first moves. . . . I for present see not but it may be of excellent use and expedition, upon many lands in England; and to say much more is needless, in regard of which hath been before spoken, and experience of a good ploughman will order it at pleasure."—Both the plow, and the language of its description are old, but on this account are not the less interesting. "As to the Coulter, (fig. 2), his truth of workman-

ship lyeth in this, whether it be Dutch or English Coulter. . . . If a Dutch Coulter, then the wheel to be very well slatted, and about ten inches high, and to go as true as possible; for the false cutting of the wheel will make you work at a great uncertainty, which Coulter is not useful, neither upon stony, gravelly, flinty, broomy, or rooty ground, but upon pure turf, or pure mould, on which it goeth very easily. The midst of the wheel had need be an inch thick, because of wearing, and so wrought thinner and thinner towards the edge round, until it comes to be as thin as a knife if it were possible, but because this Coulter is with many of high esteem, and of some advantage, and yet not much known, I will give you a figure of it, as also of the best sort of English for its compass." This old instrument for cutting the sod before the plow, in its general make-up or "style," as we may call it, is very different from those used at the present day, but the principle of construction and action is the same, namely, a revolving cutting edge. Those persons who are of the opinion that the wheel Coulter so largely mentioned and generally re-introduced some years ago, was entirely new, must on seeing this, feel in some measure the basis of truth in the wise-man's saying, "There is no new thing under the sun."

Fig. 2.—ANCIENT WHEEL COULTER.

Replacing a Horse's Shoe.—In the busy season on the farm there is often much time lost and work delayed by frequent journeys to the blacksmith shop. Many of these visits are unavoidable; but when made for the simple resetting of a single horseshoe, it is expensive. A job like the replacing of a "thrown" shoe should be done at home. It is not a difficult one, and the needed tools are few and inexpensive. A light hammer, a pair of pineers, a punch, all of which every farmer's work shop should contain for other uses, and a few horseshoe nails, are all that is necessary. It might be well to add to this a blacksmith's plane to smooth down the face of the foot, but for the simple resetting of the shoe this is not required. If the shoe is only loose, it may be tightened by driving up the old nails and clinching them anew, but if quite loose it had better be taken off, which can be done with the pineers, care being taken to not break the hoof. All the old nails should be removed by using the punch. The most difficult matter is the driving of the new nails, which must be so "pointed" at the end that they may not go into the "quick,"

but come to the upper surface of the hoof an inch or so above the sole. This can be learned by watching a blacksmith, and if he is a good-natured one he will willingly show how it is done. A little practice will render it an easy matter to drive the nails in the proper manner. As the nails are driven through, they should be turned down, and afterwards nipped off with the pineers and curved in to hold firmly. The work of resetting a shoe can be quickly done, and at a time when no loss is incurred. The morning before work, or the hour of rest at noon, may be so employed, and a journey saved, of miles it may be, to the nearest blacksmith. The shoe may come off at a time when replacing it at once will save the labor of the team and hands for a half a day or more, in which case the ability to reset the shoe is a very labor-saving accomplishment, and should be possessed by every economic and energetic farmer throughout the country.

### A Baker's Oven.

The following designs, figs. 1, 2, 3, and 4, represent a baker's oven, suitable for a village of from twelve to fifteen hundred inhabitants. It is built under ground, and usually placed below the sidewalk in front of, and adjoining the basement, or baker's work-room, towards which the openings are made to face. This position is preferred because of its accessibility in building and repairing. Figure 1 shows the position of the oven openings and doors, as they appear on the inside of the basement wall. The height of this wall is 8 feet. If the general depth of the basement is less, then a pit is made in the bottom, immediately surrounding the oven front, with a marginal step of brick work. The doors and their frames are of cast iron, and are set in the brick-work when building. The upper double doors open from the oven's mouth; below it is the door of the ash pit. The round opening above the double doors has an 8-inch iron collar, to which a smoke pipe is attached, leading to a chimney. The niche at the side, and on a level with the oven mouth, is for a yeast kettle, below which is also a grate, and ash-pit doors.... Figure 2 is a plan of the oven floor, and the surrounding walls; A, floor, "pear-shaped," and measuring an average of 9 feet in diameter; B, iron grate bars, and frame; C, C, openings to the smoke flues; D, yeast kettle (16 quarts); E, E, foundations of stone-work; F, mouth of oven; G, G, front wall.... Figure 3 is a cross section showing the construction of the foundations, ash-pit, oven arch or dome, smoke flues, and the surrounding earth....

Fig. 1.—FRONT OF OVEN.

Figure 4 represents the top of the completed oven, and the course of the smoke flues, the latter leading from C, C, in fig. 2, to the smoke-pipe opening shown in figure 1.... In building it is important that the foundations shall be solidly constructed of the best material, at least 2 feet thick, and 13 feet square, with a perfectly level surface.

The shape of the floor is then described on the surface, the grate set, the floor laid of fire-brick, and the surrounding brick-work started to a height of 4 inches. The interior mold or form of the dome is then made of sand, raising the center 18 inches. The dome is laid upon this mold, the first course being of fire-brick and the balance of ordinary hard brick. Over the dome the smoke flues are laid, also of hard brick, and the whole covered with a coat of hydraulic cement mortar, and finally enclosed with earth. In laying the flues, care must

Fig. 2.—PLAN OF OVEN FLOOR.

be taken to make the interior smooth with straight sides converging at the pipe opening from which

they may be cleaned as required. A damper is required in the smoke-pipe to regulate the draught. The smoke flue from the kettle grate may be built in the wall or by pipe leading to the chimney, as

Fig. 4.—PLAN OF TOP OF OVEN.

shall be most convenient. At completion the sand may be immediately removed from within the oven through the mouth, and the whole allowed to dry out for at least eight days, after which a slow fire may be started on the grate, and increased gradually until the required degrees of heat are obtained, and the oven is then ready for baking.

### Sawdust for Bedding.

One of our most valued correspondents writes: We have tried for two years dry sawdust in the cows' stable, and on the whole like it better than any bedding we have ever tried. It makes a more comfortable bed, completely absorbs the urine, and the cow is kept clean with less labor than when any other is used. The objection to salt marsh sods, dried, or to headlands, and dry muck, is, that they soil the cow, and make it necessary to wash the bag before milking. Straw, of all sorts, soon becomes foul, and, without more care than the ordinary hired man is likely to bestow, soils the cow's bag also. Dry sawdust is clean, and makes a soft spongy bed, and is an excellent absorbent. The bag is kept clean with the aid of a coarse brush without washing. A charge of 15 bushels in a common box stall, or cow stable, will last a month, if

Fig. 3.—CROSS SECTION OF OVEN.

the manure, dropped upon the surface, is removed daily. The porous nature of the material admits of perfect drainage, and of rapid evaporation, of the liquid part of the manure. The sawdust is not so perfect an absorbent of ammonia as muck, but is a much better one than straw, that needs to be dried daily, in the sun and wind, to keep it in comfortable condition for the animals. In the vicinity of saw and shingle mills, and of ship yards, the sawdust accumulates rapidly, and is a troublesome waste that mill-owners are glad to be rid of. It can be had for the carting. But even where it is sold at one or two cents a bushel, a common price, it makes a very cheap and substantial bedding. The saturated sawdust makes an excellent manure, and is so fine that it can be used to advantage in drills. It is valuable to loosen compact clay soils, and will help to retain moisture on thin sandy and gravelly soils. There is a choice in the varieties of sawdust for manure, but not much for bedding. The hardwoods make a much better fertilizer than the resinous timber. To keep a milch cow in clean, comfortable condition, we have not found its equal. \*

### Shocking Grain.

One of the greatest sources of loss in the grain field arises from the imperfect putting together of the bundles in shocks for curing. The common practice of shocking grain in a careless and hurried manner is, in a literal sense, "shocking." It matters not how perfectly all the other operations of the grain field are done, if the bundles are not properly set and secured from the wind and rain, the grain can not be, in "catching weather," above second class. If the shock becomes once wet through, as, if not well made, it is sure to be during a rain, the grain is very apt to grow in the shock, and poor flour, and consequently an inferior quality of bread, is the result. There is no trouble in making the shocks in the right way, if one determines to do it, and will use a little common sense. It is a common way to cut down and bind up, all the day through, and just as night is coming on, all hands turn to and set the sheaves up in the most rapid manner possible. Should a strong wind arise there are few shocks thus hastily thrown together, but will be whisked and tumbled into a confused heap. Hurried work like this is all wrong. If any farm-work should be done with care, it is the shocking of the grain.

The number of bundles in the shock may vary somewhat, 16 is sufficient. Each bundle should be set firmly upon the ground, and this can be best done by taking one in each hand at the same time, bringing their heads closely together. After three-

Fig. 2.—SINGLE CAP-SHOCK.

pairs have thus been placed in two rows, two more are to be put upon each side, thus making an oval shock, shown in outline in figure 1. The heads of all the bundles are then to be pressed together, and the cap-sheaf adjusted. This is done by taking an ordinary sheaf, with the band shoved down to within eight inches of the butt, and the top bent out into the shape of a funnel—this done, the sheaf is placed on the shock as shown in figure 2. A second form of shock, which may be considered a double form of the one just described, is shown in outline in figure 3, and consists of 16 bundles, including the two top-sheaves. Four pairs of bundles are first firmly set together, and three placed on each side. The cap-sheaves are made as in the first case, only one side of the "funnel" is left open, each sheaf forming one-half of the shock-cap, as shown in figure 4. Grain that is shocked in either of these methods, and is done by a man who cares for the quality of his work, will stand and be perfectly safe and sound, when the piles made by boys too small to set the

Fig. 3.

Fig. 4.—DOUBLE CAP-SHOCK.

bundles firmly down, or worse, by careless, wasteful men, will be wet through and approaching the state of a pile of litter.

**There is Work in America.**—A writer in "The Farm" (Dublin), tells his countrymen that America is no place for the idler, but a country where work is wanted, and where it is always well awarded. "If our laborers were equally diligent at home, our farmers would be able to give better wages, and more employment."—"Thousands of laborers think that they have only to go to America, make money, and live happy all their days."

### The Leaf-Folder of the Grape-Vine.

Grape culture is in one respect no different from any other branch of horticulture—it is a continuous war upon insects. Those who give proper care to their vines, meet with a constant succession of insects from the time the young shoots push until the fruit is well advanced. One of the earliest in this procession is found at the very ends of the developing shoots; after a few leaves and embryo

1.—THE CATERpillars.

clusters, or bunches of buds have shown themselves, something appears to be the matter at the end of the shoot. While the lower leaves go on and grow, the uppermost cease to develop; they appear to be stuck together, which an examination will show to be really the case; the leaves are held together by threads, and in the cavity thus formed will be found one or more small caterpillars, as shown in figure 1. These caterpillars, when full grown, are half an inch long, of a pale green, and on each of the rings are cream-colored warts, each of which bears a tuft of white hairs; when very young these hairs are not present. In about three weeks, during which time it has eaten leaves, and it may be the buds, it goes into the pupa state. It fastens its head portion by a few threads, and with its body standing at an angle of about 40°, and curving forward, it turns into a chrysalis, which, singularly enough, is green when on the leaves and brown when on the bark of the old wood—a measure of protection, we may suppose, against the attacks of birds. After remaining in this apparently uncomfortable position for about a week, its changes are complete, and the perfect insect comes forth a small moth, shown in figure 2, of the natural size, which, as well as figure 1, is from Prof. Riley's Third Report on the Insects of Missouri. The moth is of a tawny yellow color, with the front wings marked with white and dark-brown, while the hind wings appear like burnished copper. This belongs to that group of moths known as *Plumes*, for the reason that their wings are split into feather-like lobes. This is known as the Grape-Vine Plume, its scientific name being *Pterophorus periscodidactylus*. The first or generic name means *wing-bearer*, and the other, or specific name, is a very long word for expressing the fact that the insect has *anklets*, its legs being surrounded by tufts of brown scales. Whether there is more than one brood in a year, and in what state the insect passes the winter until the young shoots of the vine appear, are points in its history not well made out. The harm the insect does is ordinarily but little. Usually each shoot of our native vines bears three bunches of grapes, and these appear opposite the three lower leaves. Ordinarily these leaves and the bunches of buds that are to produce the grapes are developed, at some distance below the bud where the caterpillars are at work. We are aware that there are exceptions to the number of bunches produced upon a branch, but ordinarily all the buds for the crop for the season are out of the bud and sufficiently below the point at which the insect has tied the leaves together to escape, and when a bud is found to contain the caterpillars, a pinch with the thumb and finger will remove it and prevent the insects from doing further mischief. But, many will ask, will not the removal of the bud, and thus preventing the further growth of the shoot in length, injure the vine? Not at all. It is exactly what some vine-dressers would do were there no caterpillars in the bud. Grape growers differ as to how far beyond the fruit the shoot

Fig. 2.—THE MOTH.

should be stopped, but all agree in stopping it somewhere. The successful vineyardists of Missouri, including Mr. Husmann, stop the shoot just above the last bunch, while others leave two and three leaves above. This pinching is done very early, so soon as the clusters of buds can be fairly seen, and results in finer, larger, and better ripened fruit than can be had by leaving the shoot to grow in length. If the pinching is attended to in time the caterpillar is despatched before it can eat many leaves beyond those in which it incloses itself. If the presence of the caterpillars leads to promptness in pinching, it may be a benefit rather than an injury.

### Planting Fruit Trees for Ornament.

BY SAM'L. B. PARSONS.

The question is often propounded why a farm intended exclusively for fruit should not be planted for landscape effect; why a lawn could not be

for their arch, which the Gothic arch of the ruder ages can not equal. Let us take, as an example, a plot 500 feet on each side, which will have an area of something less than six acres. From the center of each side, run a line through the plot. Take the intersection of these lines for the center of the circle. In this center plant a strong, smooth and round stake. Over this drop the loop of a rope which will extend 231 feet. To the other end of this rope fasten a strong pointed stick. With the rope extended, mark the places for the trees on the segment, *A*, and plant them before touching the interior lines. Then shorten the rope 30 feet and mark the places for the trees on the circle *B*, and plant them. Then shorten the rope 30 feet more, mark and plant on circle *C* as before. Then shorten the rope 24 feet more, mark and plant on circle *D* as before. Then shorten the rope 20 feet more, mark, and plant on circle *E* as before. Thus the circles are all planted, and from the dwelling in

DIAGRAM SHOWING THE CIRCULAR METHOD OF PLANTING.

planted for ornament and only fruit trees be used. The only answer is that it is eminently proper and easily practicable so to plant both farm and lawn, that these results can be obtained, and the eye, the palate, and the pocket, all be gratified. The farmer will at once say, and truly, that to this there are two objections. The first is that he has no skill in the artistic laying out of grounds and grouping of trees, and that he can not afford to employ a landscape gardener for that purpose. The second objection is that fruit trees will not flourish when they are young without culture, that spade work is too expensive, and that he can not plow among trees irregularly grouped.—To avoid, therefore, straight lines, and yet to retain regularity sufficient to allow plowing, may not be productive of the best landscape effect, but may produce an approximation to it, and will certainly give much pleasure. The accompanying diagram will show the simple method by which any farmer can plant the space around his intended dwelling with fruit trees, and yet so preserve their irregularity that from his dwelling there will appear no straight lines.

A circle or its segment is the most pleasing line known. It is that of the sky above us, and could our eyes grasp it would be that of the earth below. The old Romans knew this when they adopted it

the center one can scarcely see three trees in line. The irregularity is there, and if vistas are wanted through the lines the trees can be left out which close it. Between these circles, with the planted trees to guide his eyes, a horse can draw a plow with as much ease as on a straight line. Circles *A*, *B*, and *C* can be planted with apple trees. *D* can be planted with cherries and the taller growing pears. *E* can be planted with plums, peaches, and the lower growing pears. The straight outlines of 3 sides of the plot can be planted with apples; the front side with that stately and beautiful fruit tree, the American Chestnut. Now, to an eye looking from the house, the interior circle will have a bare, uniform, and naked appearance. Therefore this uniformity should be broken, as in the drawing, by outlying spurs and peninsulas and islands, by plantations of low growing trees and shrubs. Next the circle could be placed a few dwarf pears or apples, or mulberries or quinces. Then could come blackberries and raspberries, and filberts and currants, and gooseberries and barberries. Then could come flat-beds of purple hazel and purple barberry, kept down by pruning. Then graded down to the level of the lawn could be the strawberries. In one or two of the round beds standing alone could be placed some rhubarb, the broad leaves of which are

as ornamental as those of the Arum, and its spike of white flowers stands up in its middle like the flower of the Yucca. We have confined ourselves to fruits, but there is no reason why the lady of the house should not have scattered along the drives her groups of roses or bedding plants. In the circle between the house and the barn evergreen trees would best hide the latter. The carriage drive from the highway could be bordered with shell-bark hickories. Thus in the small space of five acres could be made a beautiful place, giving great pleasure to the eye, and furnishing all the fruits desirable for family use. It can be made, moreover, by any intelligent man, and does not need the aid of a landscape gardener.

### The Bulbous Corydalis.

From the charming little plant with the uncouth name of Dutchman's Breeches, so welcome in the woods in April, to its gorgeous brother from China, that hangs its graceful strings of Bleeding-Hearts in our gardens in May, all of the Fumitory Family are pleasing. They have, as a general thing, handsomely cut foliage of a tender green, and their flowers have a peculiarity of form and a clearness of color that makes the amateur gardener say of each one "it's a good thing." We did not start with the intention of writing about it, but we may say with regard to one, the Plumy Bleeding Heart (*Dicentra eximia*) from the Alleghany Mountains, that, take it for all in all, it comes as near to being a thoroughly satisfactory plant as we expect to see. That is noted among other qualities for its long continued bloom. The one we would now speak of (*Corydalis bulbosa*) has an abundant bloom in early spring and is done with it. It may be said here that the *Dicentras* have two spurs, or lobes, to the flower, while in *Corydalis* there is but one, giving it a quaint one-sided appearance. The Bulbous Corydalis is a native of Europe and Asia and is thoroughly hardy. It has a solid bulb or tuber about as large as a hickory-nut; the stem, 6 or 8 inches high, has cut leaves, and at the top is a raceme of flowers of the size and shape in the engraving. A drawing can show size and shape, but the color must be left to the imagination. We may call it purplish-rose or rosy-purple, but that does not give an exact idea of the tint. As we looked out upon a closely planted bed of it in April, it occurred to us that we had not seen a more thoroughly spring-like tint—lilac does not describe it. It is the tint that suggests spring days, spring flowers, and—the spring fever. The plant keeps in flower two or three weeks, makes a strong leaf growth, and then having done its duty in giving us pleasure by its season of bloom and having provided for another next spring, all above ground soon disappears, to be thought no more of until another winter shall have passed, and spring has come around again.

### The Clover Root Borer.

Mr. I. S. Peer, of East Palmyra, N. Y., sends a letter and a package of clover, both of which plainly show that he is very badly troubled with the Clover Root Borer. None of the insects are to be found in the honey-combed, and thoroughly eaten roots, but we have no doubt that the destruction of the plants was caused by the larva, or grub, of the

beetle, known to science as, *Hylesinus trifolii*. This pest is rather new to us, but has been known in Europe for many years. Professor Riley thoroughly investigated the insect, and published his results, with an illustration of the beetle in its various states, in his Report for the year 1878. The *American Agriculturist* for November, 1879, gives an illustrated article on this Clover Root Borer. Mr. P., writes: "On examination, I found that I could with the side of my foot scrape the roots of the clover all together. These were entirely dead, or perhaps a leaf or two alive, but very small. The stalks that looked at all healthy, would not average four to the square foot. I had 21 acres, all of which was more or less effected, and I am now plowing it up for corn."—This is certainly a destructive insect, and its advent a serious matter. When it works in this way, in such destructive numbers, the only remedy is a total withholding of the clover crop, throughout the district. Half-way measures will

THE BULBOUS CORYDALIS (*Corydalis bulbosa*).

do no good: there must be co-operation in the work by every farmer in the neighborhood. If one farmer continues to grow clover—or tries to grow it, he will merely provide insects to stock the fields of others, when they resume its cultivation. No direct remedy which will kill the insect is yet known, nor is it probable that one will be found, the application of which will be practicable to insects that work below the surface of the soil.

**Water Cresses without Water.**—Several persons in England have reported their success in growing Water Cresses in the garden. We gave, several years ago, Mr. Hibberd's method with pots and tubs, but this growing them in the garden will meet with more general favor. No definite directions are given; it is merely stated that the beds were sown sometime in summer, and that a bed sown in well prepared ground will continue for several years, as the plant reproduces itself from

self-sown seed. The difficulty with us will be in carrying the plants through the hot, dry summer, and those of our friends who desire to experiment with Water Cresses in the garden, should select a place that is shaded during the hottest part of the day. Seedsmen generally have the seeds for sale.

### Why Not More Currants.

Perhaps when we consider their real value, currants are more neglected than any other of the small fruits. Their value in the family is too well known for us to enforce, but their market value is greater than that of most, if not all other fruits. By this, we do not refer altogether to the money received for them, but to the fact that there are not so many drawbacks to getting the money at all. "If currants are ripe they may be picked to-day, tomorrow, or next week, and must not, like the strawberry and raspberry, be picked by the clock. Currants sustain less damage in transportation; the delay of a train or boat by accident does not cause the loss of the crop; if the fruit does not sell within a few hours after it gets to market it will keep until the next day. As to the actual profit from an acre of currants we have no figures, but we notice that those who have had an acre are very apt to add another to it, which is quite as expressive as if we saw their account of sales. But the currant worm! Whoever finds that an obstacle should not cultivate currants—or any other small fruits. We do not know of one of them that will yield profitable crops without care, and the currant requires on the whole less care—currant worm included—than any other. Buy some currant bushes, get good big ones; plant them up against the fence, setting them so close to one another that their stems will touch and soon interlock; acting upon the principle of "the more bush, the more room for fruit," do not cut them—in short, follow the too common treatment of this fruit, and we have every reason to believe that currant culture will not pay. This is not the method of those who are increasing their plantations.—*The Soil* should be as good as can be had, and especially free from excess of moisture; no fruit will give a better return for manure.—*The Varieties.* Our largest growers depend upon La Versailles, or as more generally called Versailles, and White Grape. So far as we have seen, these, of the true sorts—and this is important—will, under good culture, do all in size of fruit and productiveness that any currants will do, though it may be that some others may be found to prolong the season. There is so much confusion among currants, that if one appears to have desirable qualities it is difficult to obtain it true to name—not from intentional wrong on the part of the nurserymen, but currants are so much "mixed."—*Cuttings or Plants?* Generally those who have plantations have so much surplus wood from pruning that they are glad to sell cuttings at a very low rate; one can purchase these and plant them in a bed, or buy plants one or two years old. Of course the purchase of plants will give one fruit a year or two sooner, while the outlay will be more. Cuttings should be planted in fall, and it is quite doubtful if they can be had in spring. *Planting* is better done in fall, but may be done in spring, but the plants should be taken up so soon as the frost will allow, as they start into growth very early. If lifted after the buds have pushed, this young growth may be injured, if not destroyed, in transportation, to the injury of the future of the plants. In setting out the bushes, four feet each way is the least distance for healthy growth and comfortable working, while five, or still better six feet, will in the end give better results than to set close. At planting, some pruning may be needed, but this will depend so much upon the former treatment and present condition of the plants that no directions can be given. *The Currant Worm* is as likely to come upon young bushes as upon old ones; hence the plantation should be looked to daily, and if any ragged leaves are seen, look for the enemy. On small bushes much may be done by hunting for the eggs, which are upon the underside of the leaves, especially those near the ground. When the enemy is discovered, use

powdered White Hellebore, either dusting it from a bellows, or mixed with water, as we have described at the proper time, in Notes about Work.

### The Raspberry Fungus.

So soon as the leaves of the raspberry and blackberry bushes, both the cultivated and those growing wild, have reached two-thirds their natural size,

THE RASPBERRY FUNGUS.

and sometimes before, they are frequently noticed to be covered on the underside with a number of large patches of orange color. This spring we have received numerous letters, containing specimens of the plants affected by this trouble with the anxious and important question: "What can we do; for this disease is destroying whole rows of our raspberry bushes?" The trouble is a parasitic fungus—a little plant which sends its fine microscopic 'roots' through the substance of the young growing leaves, and after a short time breaks through the surface and develops a vast multitude of minute spores constituting the fine dusty powder with a rich orange color. This fungus, unlike the grape mildew and other similar and comparatively slow acting parasites, is so rapid in its development, and has its course so nearly run by the time it shows itself, that up to the present time no preventive has been found. So soon as a bush is seen to be affected—and it usually attacks the whole raspberry plant if at all—the best way is to cut it down and burn it at once, thus clearing the ground of a useless bush and at the same time destroying a vast multitude of spores—or seeds as they might be called—that would otherwise find their way to other bushes and there reproduce the trouble.

### Horseradish Culture

There are certain crops that may be classed as "uncertain." There is a certain demand for them, but this cannot be increased, as the consumption is limited; and a small excess in the production, causes an over supply, and prices fall. Such crops are constantly fluctuating; the high prices obtained in a year of scarcity, induce many to grow them, and the next year will be one of glutted markets, and low prices. Again the culture will be abandoned by all but a few, and prices go up again, and so it continues, an alternation of extremes. Those who grow such crops in moderate extent year after year, no doubt make money in the long run, while the outsiders, who take them up only after a season of high prices, not only make noth-

ing themselves, but prevent the regular growers from making it. Hops are such a crop, Tobacco to a certain extent another, and on a smaller scale, Horseradish. Just now, to judge from inquiries, there is likely to be another Horseradish boom; as many ask how to cultivate Horseradish, indicates that those who have never cultivated the crop, think of trying it; indeed, some know so little about the matter, that they ask where seeds of Horseradish may be had, and how much is needed for an acre! Such are evidently not aware that a Horseradish seed would be a curiosity, that few persons have ever seen. The plant blooms freely, but, in this country at least, fails to form seeds. Horseradish is always grown from sets, obtained in preparing the roots for market. These are about the size of an ordinary lead-pencil, and 4 to 6 inches long. As they should be planted "right side up with care," the lower end is cut with a slant, and the top square. These sets are to be had of the seedsmen generally. Regular market gardeners grow Horseradish to the best advantage, as they put it on the same ground with their early Cabbages or Beets, planting it between the rows. Early cabbages are set 18 inches apart in 2 foot rows, and the sets are put in midway between the rows, and as far apart as the cabbages; when grown between beets, those are in rows 18 inches apart, and the sets put in every two feet between the beet rows. When it is grown as a crop by itself, the Horseradish sets are put at the same distances, i. e., 18 by 24 inches. When grown with other crops, it is kept down in the hosing, until they are off, when it has the ground to itself. The sets are put in with a long dibble, taking care that the top of the set is about 3 inches below the surface. When grown between market garden crops it is always sure of a rich soil, and fine roots are produced; when grown by itself, the soil should be well enriched. It should always be dug in the fall or early spring, and never be allowed to grow more than one season. It may be planted any time during the month of May. In the family garden the same rule should be observed, i. e., to always dig it after one season. If left longer it gets such possession of the soil that it is difficult to eradicate it, and it becomes a troublesome weed.

### Stinging Caterpillars.

Notwithstanding that caterpillars have no stings, we every year have complaints from people who are "stung" by them. Even the great, green caterpillar, popularly known as "Tomato-Worm," has actually been accused of stinging, and is looked upon as dangerous on account of the ornament it wears at its tail end. But while caterpillars have no proper stings, several of them are not to be handled roughly, as they have very sharp hairs which penetrate the flesh and produce a disagreeable sensation similar to that caused by a sting. The hairs of some plants possess similar irritating properties, notably those upon the pods of

SADDLE-BACK LARVA.

a species of *Mucuna*, one of the Pea Family, called Cowhage, which name has been singularly corrupted into "Cow-itch." These hairs, when examined by the microscope, are found to be exquisitely sharp, and furnished with still smaller barbs, all pointing backwards, and tending to prevent the removal of the hair. A quite large caterpillar, the larva of the Maia Moth, is found upon the Oak trees; when full-grown it is about 2 inches long, and at that age bristles with much branched spines, which enter the skin very readily and cause much pain. But the caterpillar most complained of, and of which we have several specimens sent every summer, is popularly known as the "Saddle-back Caterpillar." It is so striking in its colors and markings, being quite unlike any other caterpillar, that it at once attracts attention, and as the discoverer is likely to wish to show the curious creature to others, he picks it up and finds that it is not so innocent as it looks. The engraving, from Packard, shows the insect of its real size. The body is reddish, with a very handsome light-green "saddle-

cloth" spread over it; in the center is a broad elliptical reddish-brown spot, edged with pure white; a most striking contrast of colors. At the front and rear are pairs of projections or tubercles which are bristly with black hairs, which, when the insect is handled, cause the stinging sensation. This caterpillar feeds upon most fruit trees, raspberry bushes, and even on Indian Corn, of the silk of which it is said to be particularly fond. The perfect insect is a moth about an inch and a half across, of a rich, dark velvety brown, with a few small golden spots. It is never abundant anywhere.

### A Simple Wire Stretcher.

A correspondent in Virginia, sends us very neat sketches of a device for stretching wires in a vineyard, for a fence, or wherever else a horizontal wire is to be stretched tight. We have no doubt that this affair will do the work, and do it well, but as it is too much trouble to make it and to use it, and takes up quite too much room when not in use, we do not give it, preferring a much simpler stretcher that we have used for years, and which is as effective as any device can be. If we mistake not, we found it in use in the vineyards of Steuben Co., N. Y. It is simply a cylinder of hard-wood about a foot long, and perhaps 3 inches in diameter; this has a small hole in the center for the wire to pass through, and a hole near each end, to admit a half or three-quarter inch iron bar, these holes being bored in opposite directions. This piece of wood, which may be a section of a limb of an apple tree, or any other, sufficiently strong, and may be formed naturally, true enough for the purpose, and two iron bars 18 inches or 2 feet long, make up the whole machine. The manner of using is shown in the engraving. The holes in the post through which the wire passes, should be at least half an inch in diameter, for the convenience of fastening. The wire being made fast to the post at the further end of the row, is passed through the opposite one, and through the small hole in the center of the cylinder; the rods being in place, turn the cylinder gradually—two persons are handier than one at the work—and when the wire is sufficiently stretched, one holds the arms to keep all taut, while the other drives a wooden plug, made ready for the purpose, into the hole in the post. This should be driven in firmly enough to keep the wire from slipping, and when driven home should project beyond the post for 2 or 3 inches. Unwind the wire from the cylinder, give it a turn around the end of the plug, and the job is done. If it be desired to slacken the wires in winter, unwind the end from the plug, drive it out by means of an iron rod, at the other side of the hole, and the wire can be as slack as desired.

WIRE STRETCHER

**Liquid Manure for the Garden.**—It is a well established fact that the liquid is more valuable than the solid excrement of animals. It is much quicker in its action, because all the elements are in a soluble state, and are, when applied to the soil, more uniformly distributed. There is a great waste of this valuable fertilizing substance partly from a lack of a proper appreciation of its value, but mostly from a failure to provide some simple and inexpensive means of saving and storing it. The extra cost of building the stable and grading the barn-yard so that all the liquid manure may flow through a channel to a tank or tight bottomed pond, is trifling; but when the provision has been made, and the fertilizing elements thus saved are put to use on the garden, near by, the gain is marked, and the returns for time and trouble are more than satisfactory. Try it for yourself.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### A Fungus Fern Bracket.

There is no class of plants the individuals of which possess more beauty of form and grace of outline than ferns. They are generally and generously distributed through the rocky highlands and wet lowlands, and if these fine, delicate plants are not employed to lend their grace and beauty to the household, it is our own fault. It must be admitted that there is some work in fern-collecting, but with a little care it can be made a pleasant task. A large portfolio is the most convenient for gathering the ferns, which should be well supplied with smooth sheets of paper, into which the fronds, as their leaves are called, are to be carefully placed so soon as they are picked. If a basket or box is used, the delicate leaflets are apt to get crushed or broken, and if not kept wet will soon wilt and roll up, and are spoiled for pressing. After the portfolio is filled, or a sufficient quantity has been gathered, the fronds with their papers should be placed between other papers (newspapers will answer) and pressed. The simplest press is the best; putting the pile of papers under a board with a heavy stone or other weight upon it, is the ordinary and best method of drying and pressing plants. Those who do not find stones abundant can use instead, for a weight, a box containing old iron, or even dry earth, though in that case the box must be made very tight, by pasting paper over the corners. If much pressing is to be done it will make

A FUNGUS BRACKET FOR FERNS.

the work easier if a piece of hoop be fastened to the box as a handle to lift it by. If the box has a cover, and the whole is papered, the affair will look all the neater. The specimens will need to be changed into fresh, dry papers the next day, and at intervals until thoroughly dried. In changing the drying papers, do not disturb the ferns; they are to remain in the fold of paper in which they were first placed, and in changing, the paper with the plants is to be placed between dry papers, while the damp dryers are to be exposed to the sun for a short time. When dry, the ferns are to be put away in the folds in which they were dried, and kept under sufficient pressure to prevent them from curling up, until wanted for use. The dried fronds may be used for decorative purposes in various ways. One of the most attractive forms is given in the accompanying engraving, taken from Mr. J. H. Batty's new work on "Practical Taxidermy and Home Decoration." The design is a Fungus Fern Bracket, and requires a member of another family of plants, the Fungi. Those who

go much into the woods will have little difficulty in finding specimens of this kind; they are found attached to trees, projecting like a little shelf not far from the ground. These are often called Agarics, an incorrect name; their proper botanical name is *Polyporus*. They grow with the smooth surface upwards, the reverse of the position in the engraving; are quite common in the woods, and some specimens are of themselves curious in structure and even beautiful in appearance. Having the fungus, it is to be mounted upon a shield, or back, made by cutting out a piece of thin wood in any desired pattern. The shelf-fungus is glued to this back near the bottom. The upper surface of the shelf may be covered with fine mosses that have been dried for the purpose. The moss should be glued on rather compactly, as it furnishes a bed into which the stalks of the fern fronds are stuck, and thus, aided by glue, are held in place. The arrangement of the fronds will depend much on the individual's taste, but, as a rule, the largest should be at the rear, with the smaller and more delicate specimens in the foreground. Fine grasses can be added, and here and there a butterfly may have seemed to have alighted upon the fronds, but to our taste simplicity is a prime element of beauty in all matters like this, and it is easy to overdo.

### Home Topics.

BY FAITH ROCHESTER.

#### Bachelor House-Keeping.

I suppose everybody knows what "grass-widow" means—a woman living temporarily absent from her husband. I can think of no corresponding term to apply to a man in like condition, unless it is "grass-widower." I know of one who is just setting up his cabin on a northwestern prairie, prepared for a summer campaign of "breaking" prairie-sod. A boy of fourteen is with him as "chief cook and bottle washer." I feel a deep interest in their work, particularly in the house-keeping. The boy's success or failure in cooking, washing, etc., will bring credit or discredit to his mother—and that's me. I have lately heard the father inquire anxiously concerning his capabilities—"Do you know how to cook oat-meal?" "Can you make such graham bread as this?" "Does he understand the knack of making dried apples eatable?" "You know how mamma seasons the macaroni, don't you?" etc. Both are very fond of milk, and if they get a cow, or find good milk for sale close at hand, the cooking and eating business will be simplified. Milk goes well with almost everything that our folks eat, as we never use pickles, and vinegar very seldom. To make sure of cooking the oat-meal, cracked wheat, rice and hominy, properly, they have taken along a steamer made after the farina-kettle plan. They are directed to use one part oat meal, rice, hominy, or cracked wheat, to four parts of cold water in the inner kettle, with plenty of water to keep up boiling in the outer one.

To secure good graham bread, they have provided the best of graham flour and the dried "National Yeast Cakes." The cook will set a thin sponge at night, with half a yeast cake, and flour and warm water enough to make a large dripping-pan loaf (all they can bake at one time in their oven), and in the morning he will add sugar and graham flour until he has a stiff batter well beaten. This will be turned into the buttered bread-pan without kneading, allowed to rise quite light and then baked. It is pretty sure to be good every time, for the same cook has gone through the same movements many a time, simply helping his mother, but unconsciously educating himself to be a great help to his father in this emergency, and possibly to himself later in life.

#### To Make Dried Apples Eatable.

Concerning this fine art there is great lack of knowledge among the people. I don't know the various ways by which they go astray, but I do know that if you have good dried apples, and cook them properly, you may have delicious and wholesome sauce. I have heard of their being cooked in an iron kettle, and of course they were not liked. No rusty tinware is allowable to cook or keep any kind of fruit. Bright new tin, a porcelain kettle,

or stoneware may be used. Look over the slices or quarters, removing not only cores, but the decaying portions—those that have partially decayed while drying, and are black and of bad flavor. A few such slices spoil the flavor of the whole dish of sauce. If dried apples are not soaked over-night, three hours are not too long to give to their slow cooking. It makes no difference in the result whether they are soaked or not. Dried apple sauce is high in favor in our family. We use a variety of fruit, but none more than apples, in one form or another. Good apples, properly dried, come in well after the season for fresh apples is over. The cook referred to above, expects to cook a gallon jar nearly full of apple sauce at a time, for himself and his father. He will fill the jar less than a quarter full of the washed slices (if you soak them be sure, and do the washing first, and then cook them in the same water in which they were soaked), and add cold water until the jar is three-fourths filled. After a time they will swell and threaten to run over, but they may be stirred down and will soon shrink to the original proportion. When they have cooked thoroughly soft, sweeten them with the best of sugar, and boil a few minutes longer. Nothing is better for flavoring apple sauce than good maple sugar. We always use the granulated sugar. We like to cook fruit in an earthen jar because it can be set aside and kept in the same vessel. It never imparts any taste, and is easy to clean. The gallon and half-gallon jars in which my butter often comes, prove very useful about the house, though I can return them when I choose. I have used the stone jars for years, and have never broken one by cooking, unless the fruit, or other contents of the jar, has boiled dry. They cannot bear sudden transitions from great heat to severe cold, or the contrary.

#### Soaking the Clothes.

I am afraid our inexperienced house-keepers, before referred to, will get into trouble by soaking their clothes too much. I suspect they will often have to use hard water for washing. The boy has seen me soaking the clothes over-night, sometimes lately with the idea that I was gaining time, but I think now that I have usually lost more than I have gained by the operation. A brief soaking in warm suds just before washing is much more effective, I think, than all night soaking in clear cold water. To soak clothes in hard water is worse than useless.

#### To Prepare Hard Water for Washing.

I cannot find definite directions anywhere, and perhaps no exact rule can be given, since water, with lime as an ingredient, has different degrees of hardness. Some soften a barrel of water at a time, by tying ashes in a bag—two or three quarts for each barrel, I have been told—and leaving this in the water over-night. The same ashes would not do for the next barrel, of course. Others make a white lye by boiling a kettle nearly full of ashes and water. This is added to the hot water in the tub, or, better still, to the water heating in the boiler. In the latter case, as the water heats, a white scum rises, which can be skimmed off, and leave the water clear and soft. Miss Parloa, in an excellent little book, entitled "First Principles of Household Management," gives very clear directions about washing, but concerning the use of hard water she only says "if the water is hard, add a little washing soda or borax." The most expensive way to soften the water is to use borax, but it is the most satisfactory method. It is a great aid in washing with soft water, and whatever is not taken up in softening the hard water, remains to make the cleansing of the clothes more easy and effectual.

**Water Filters.**—Impure water is perhaps the most common source of those diseases frequent at this season, and known as summer complaints. The hot weather favors the development of those low organisms that only the microscope reveals, but are at the same time very dangerous when taken into the system in any considerable quantities. At this season also water is the most scarce, and it often happens that other than the regular source of water, the well, is resorted to for water for household use. In all such cases, if one is not sure that the water is pure, it should be filtered,

and this can be easily done. Secure a quantity of charcoal and make it fine. Put the charcoal into a flower pot set in the top of a tall jar, and pour the suspected water upon the mass of charcoal. It should be observed that all the water passes through the bed of charcoal, and that not too rapidly. The best way is to have a tall vessel that is provided with a stop-cock or faucet for the drawing off of the filtered water below. But if such a vessel is not at hand, filter the water any way that it is possible. The point is to pass the water through the charcoal that the disease germs may be removed, and thus prevent them from getting into the system.

### Yeast: What Is It?

In the process of fermentation of many substances, and in the making of beer, a grayish foaming mass separates and is known as Yeast. When seen under the microscope, this substance is found to consist of countless minute bodies, called cells—some of which are shown very much magnified in the accompanying engraving. These little bodies represent so many living, growing plants, and a globule of yeast that may be held upon the point of a pin is, so to speak, a whole forest of vegetable forms. These plants are very low in the scale of life, as their simplicity of structure would lead one to conclude. The method of increase,—which is very rapid—may be illustrated in the following way: Suppose we have a body like a link of sausage made of thin rubber, and is constantly enlarging in all directions. After it has grown to a certain size, a string is tied around the center, and the two ends are literally “tied off” by a drawing down of the string, thus forming two little sacs out of the larger one. In the same way the two new cells, or sacs, increase in size, and in turn are divided into two similar small ones that grow and divide, and so the process continues as long as growth lasts.

This is what takes place with the yeast cells, the time for the growth being very brief, and of course the division is not accomplished with any thing in the shape of a string: it being self acting—a part of “the nature of the plant” as one might say. All growth, whether it be of the most complex animal, or the simplest vegetable, like the yeast plant, is of this same kind, namely: cell growth and division.

But what is the use of this plant which we have found to be so simple in its structure? It, like

THE YEAST PLANT.  
(*Saccharomyces cerevisiae*.)

every other living thing, grows only when the necessary food for its consumption is at hand, and as it grows it produces certain changes in the substance upon which it feeds. It is in these changes

—or the power to produce these changes that its value in the household lies. As the yeast plant grows, it decomposes its food, and, among other things, causes the escape of a quantity of carbonic acid gas; in other words it produces a fermentation. The most common domestic employment of fermentation is for the raising of bread. The yeast is added to the dough in the early stage of bread-making, and as it furnishes all the elements for the growth of the yeast plant, that soon begins to grow, feeding on the flour, at the same time producing a quantity of carbonic acid gas. This gas tries to escape, but is held in by the tenacious dough, and thus becoming filled with the forming gas, the dough is made light, and, in baking, the gas is still more expanded, making it, when baked, a healthful article of food. This yeast plant may be dried without losing its life; and as such it is a common article in the market, in the various forms of yeast. The “Indian Yeast Cakes,” extensively used in the country, are composed of the yeast plant, dried with a mixture of Indian meal and an infusion of hops. Whatever be the substance used, the end is the same; the development of a fermentation to produce an evolution of gas for raising the dough, and thereby making the bread light and wholesome. It is then a little microscopic plant of the fungus

group that does so much for our comfort and health, and even though some of these low plants are our worst enemies, we must not forget our friends.

### A Summer Lamp Shade.

Even lamp shades have their times and seasons. In a large city the coming and going of different wares presents a subject for the study of the curious. Take this Lamp Shade as an example. About a fortnight ago, in passing a large lamp store, our attention was arrested by the display on some lamps in the window, of a shade that struck us as very pleasing in appearance. Soon after we saw in the window of a “fancy store” a lot of the shades of various colors. A few days ago we went to one of the principal stationers on some errand and found a great lot of the shades there, and were informed that they were “all the rage.” To-day we had the latest evidence of their popularity in the appearance of salesmen upon Broadway with baskets of the self same shades. The shade is in itself re-

Fig. 1.—METHOD OF FOLDING THE PAPER.

markably pretty, exceedingly cheap, and not difficult to make. It is best suited to lamp shades of a globe-form, though it will answer for others. The material is tissue paper, which may be had in any desired color. To make the shade a square piece is required, a whole sheet or a half, according to the size of the lamp-globe. First fold the square piece once, which will make a fold twice as long as wide, as in figure 1; then crease this in the middle, *A, B*, which will divide it into two small squares, *A, B, C, D*. Begin with one of these squares, that at the right hand, fold *D* over to *A*, and it will give the crease *B, C*; then fold *B, D*, over upon the line, *B, C*, and it will give *B, E*. Next carry *D* over to a point half way of the upper edge of the next square, to *H*; this will give the line, *B, G*. The folding is to be done in such a manner as to make a sharp crease each time. Having creased the right hand square, as shown in figure 1, treat the left hand one in the same manner, beginning with the fold from *B* to *F*. When this is done, turn the paper over and fold between the present creases, in the opposite directions; this will have the effect of folding it like a paper fan. When the folding on this side is finished, the whole will appear like figure 2.

Fig. 2.

Now carefully open the whole, and you will have a funnel-shaped plaited affair—which is to be held by the center and carefully drawn through the hand several times, increasing the pressure upon the paper each time; this is to fill the paper with innumerable irregular creases, and to give to the shade that peculiar crimped, crape-like appearance that constitutes its special beauty. When completed, the shade appears as in figure 3. When used, the top or point is to be cut away sufficiently far down to give an opening of the required size to fit it to the lamp-globe. The shade in use is shown at figure 4. It has a beauty quite remarkable when we consider the simple means by which it is produced, and it is useful as well as beautiful; the lamp adding greatly to our personal comfort.

### Progress in the Kitchen.

To the old housewife in her declining years, perhaps nothing is more amazing than the great changes that have taken place in kitchen furniture, and methods of doing cooking, etc., since she was a girl, fifty or sixty years ago. Our grand and great grand mothers with a crane, some pot-hooks, and a brass-lined skillet or two, worked over the blazing open fire-place, until their faces were almost as red as the fire itself.

They did not dream of the perfect range of the present day, in which the heat is economized, and only allowed to cook that which ought to be cooked. When baking was to be done, a great fire had to be built in a great oven, and after the bricks were heated, the fire and ashes were removed, and the bread, cake, etc., placed in, after the proper temperature had been obtained.

Now everything is so nicely arranged, that without getting overheated, the cook can do her work, and not a particle of smoke need escape into the room. Instead of the brass kettle with its constant scouring to keep it clean, we have the tin or porcelain lined stew-pans, kettles, etc., which to keep them clean only require the simplest of washing and wiping. At the present day, there is a handy little utensil for the doing of each of the simplest things in the kitchen—a list of which would be a long one. From the flour sifter, through all the processes of bread-making, to the handy toaster, everything seems complete in labor-saving aids and helps. Contrast the safe hanging lamp, with its abundant and cheap light, with the miserable tallow dip of a half century ago, which the woman made herself, and was constantly snuffing that it should not go out in smoke. Even in the matter of wash-day appliances, etc., the contrast is fully as great; instead of the old pounding, and hand-wringing, the whole work is done by machines that are easy to run, and do the work quickly, and in a thorough manner. With all the inventions and vastly superior methods of doing the work of the house, are our soups, and breads, pies and sauces, much better than those our grandmothers made?—They

Fig. 3.

Fig. 4.

may not be, but the time spent in making them is shortened. They gave their minds, and too often we may add regret their bodies, to the work of the kitchen, while with the same house to keep, the woman of to-day can spend a portion of her time in the library. The cook-room may be “a laboratory, where a fine chemistry can transmute grain cells and meat fibre into the fuel of a finer flame, the support of a richer flesh and blood, abler and stronger to do, than flesh and blood were of old.” In the material progress of the age, the means for lightening the labors of the kitchen, as well as the various duties of the household have not been forgotten, and this is as it should be.

BOYS & GIRLS' COLUMNS.

The Doctor's Talks.

Some boys have asked me to tell them how to make a Balloon. I wish they had reminded me of it sooner, as I might have talked about it last month, and you could have had your balloons ready for the Fourth of July Celebration. I believe in balloons for the 4th.

Balloons and Chinese lanterns are a great deal better than crackers and fire-works to celebrate with. They do not cost so much to begin with, the lanterns will last from year to year, though I must admit that balloons are not very lasting; to be sure they are not dangerous, and do not make a bad smell, but we shall by and by learn to show our patriotism without

Fig. 1.—STARTING THE BALLOON.

either burnt powder or burnt fingers. In former times people used to always speak of them as Air-Balloons. I recollect that when I was a mere youngster, I heard some old people talking about an *abaloon* that was to go up at some place, and I was in great mental distress to know what the wonderful thing might be, until I could reach home and have it explained that it was an Air-halloon—that was discussed. You may think that these "Talks," where we have been trying to look into the why and wherefore of various things, is not the proper place for 4th of July and balloon talks.

WHY DOES A BALLOON GO UP?

We might answer this by saying that all balloons do not go up, and none will do so unless certain laws that we have been talking about are observed. We may look upon a balloon as a mere toy, to afford amusement, or as a piece of apparatus for illustrating some of the facts of science. I do not know why we can not regard it as both. If you wish a body to rise through the water you know that it must weigh less, *i. e.*, contain less matter than the same bulk of water. For a body to rise in the air it must weigh less than the same bulk of air. We have not yet had much to say in our Talks about Air and other gases, but I suppose you all know that air has weight. If a vessel holding 100 cubic inches with the air thoroughly taken out of it, is weighed, and then the air is let into it, and the vessel is again weighed, it will be found to be heavier than before by 30 grains. That is the

Fig. 2.—SHAPE OF PIECES.

average weight of the air—100 cubic inches weigh 30 grains. If we imagine a column of air one inch square at the earth, and reaching, of that size, all the way, as far up as the air extends, which is supposed to be about 100 miles, that column would weigh 15 pounds. A halloon then must in the first place be of very light material, and then must be filled with

SOMETHING LIGHTER THAN AIR.

The lightest gas known is Hydrogen—that is about 14 times lighter than air, and is on some accounts the best for filling balloons, and has been used a great deal for that purpose. But there is another law that prevents it being the best material for balloons, and that is the law of diffusion of gases—sometimes I may talk to you about this: suffice it to say that gases of unlike weights, when separated by a porous partition, tend to mix; the heavy gas passes through the partition into the lighter one, and the lighter gas passing into the heavier one—and the lighter gas will pass through as much quicker than the heavy one, as it is lighter than that. So it is very difficult to hold hydrogen in a balloon. For this reason, and

for its greater cheapness, illuminating or street gas is generally used, and as this is several times heavier than hydrogen, the balloon is made larger. But

IN THE FIRST BALLOON,

neither of these gases were used. The first balloon that was made did not go very far. It was of silk, had square sides, and went only up to the top of the room. When hydrogen gas was first discovered, it was tried in paper balloons, but they would not hold it. Two Frenchmen, brothers, named Montgolfier, were paper-makers. They tried hydrogen, and it would not work; then they tried to invent another gas by burning wool and straw, and that did answer. But it was not the gas from the straw and wool that made the balloon ascend. In burning these, the air was heated, and as a given bulk of hot air is lighter than the same of cold air, the first that went up was a hot air-balloon, though it was then thought to be due to the gas from burning wool. In making a halloon for our purposes, we use paper and hot air. We will not give any more of the early history of balloons, but go on

WITH MAKING THE BALLOON.

The materials needed are Twine, Paper, Flour-paste, and a brush to put it on with, a piece of willow or rattan for a hoop, a few feet of fine wire (copper is best, but iron will answer), some bits of sponge, and a few ounces of alcohol. Besides you will need a lot of old newspapers and some patience and skill. The sheets of tissue paper are 30 by 20 inches. As neither of these lengths is enough for a good-sized balloon, they should be pasted together, two sheets joined by their shorter sides, will make strips 60 by 20 inches. Our balloon, fig. 1, if 60 inches high, will, if a globe, be 180 inches in circumference, that would require 9 strips, but as we do not want it to be quite globular, and an even number of strips, as we shall presently see, are required, 8 pieces will be better. We shall want, then, 16 sheets of tissue paper. It will be safer to have a few extra sheets to make repairs in case of accident. The balloon may be all of one color, but it will look better of two, white and blue, or white and red are the most pleasing; or all three may be used, three strips each of red and white, and two of blue, or three each of white and blue, and two of red. In procuring the paper, see that there are no holes in it, or, should any be discovered, they must be stopped by pasting a small piece of the same paper over them. Use well-boiled smooth flour paste; it is a great deal better than gum, which dries hard and will crack when bent. Paste the sheets together in pairs, lapping them about half an inch. When these are dry you will be ready to cut out to the proper shape. If the balloon is to be a globe, the pieces will be of the shape of fig. 2, *a*, each with the end cut off to form the mouth. But a pear-shaped balloon is handsomer and easier to manage, and I think altogether better. For this the pieces have the shape given in fig. 2, *b*. If there is any rule for cutting out the parts or gores, I do not know it. In talking about making a balloon, as in many other matters, I have to go back a great many years, and, as a sailor would say, "overhaul my memory." Indeed I found that there were so many points about making the balloon, that I could not recollect about, that I went to work and made one, in order to be sure I was right. To get the right shape, then, for the parts, take a piece of paper, 60 by 20 inches, fold it lengthwise, and mark out a pattern. When it is to your liking cut it out, and use it to cut the tissue paper by. If you have large and sharp shears, all 8 pieces may be cut at once; otherwise you must cut fewer at a time. Next comes the most difficult part, the pasting. Take it easy, and don't get hurried or fussy over it. Tissue paper, when wet with paste, is very delicate and frail, and will tear very readily. Be careful with the paste, and should any get upon the paper where it is not needed, wipe it off gently with a cloth, and let the place dry before another piece of paper is laid upon it. Having arranged the pieces as you wish the colors to go, you will begin to paste. Lay down a piece of the tissue paper, then lay another upon it, with its edge half an inch within the edge of No. 1. Paste upon this projecting half inch of No. 1, and turn it over and paste it upon No. 2, begin at the curved part, the top of the halloon, and paste the edge over a few inches at a time. When the whole edge has been pasted, lay piece No. 3 upon No. 2 in the same manner, half an inch back from the edge. If the pasted edge of No. 1 was from you, that of No. 2 will be towards you; this being done, lay No. 3 on No. 2, and paste in the same manner, and go on until all are pasted together. When you have pasted the last, No. 8, you will have your halloon, folded like a fan, with alternate edges, in and out. Now comes the most difficult part, pasting the last edge—pasting the edge of piece No. 1 upon that of piece 8. By bending the other folds out of the way, you can, without much difficulty, paste the edge from the top down to the widest part, about a fourth of the way; then stop and let it dry—being sure that all the pasting is perfectly dry, you then unfold the balloon, *i. e.*, take out the plaits. Now take a piece of cloth of some kind, glazed cambric or calico is best, cut

out a circular piece about 2 inches across, and put this on the inside, where all the pieces come together, when that is dry, paste a similar piece of tissue paper on the outside. Now having the balloon unfolded, you will find but little difficulty in closing up the rest of the last seam. Let that dry, and by means of a large needle you can put a strong thread or small cord through the piece of cloth in the top, and make a loop to hang it up by. When hung up you can put in the hoop; this is to be as light as possible; a small willow, split if not small enough, a split rattan or whatever is most convenient to make the lightest possible hoop. Cut the mouth of the bottom even, and put in the hoop, pasting the edges of the paper over it. Stretch a very fine wire across the hoop in two directions and the balloon is done.

TO SEND UP THE BALLOON.

Before starting out, see that there are no parts of the balloon that stick together, and that all the folds are out. You will need two bits of sponge about the size of English walnuts. One of these should be secretly attached to a fine wire about 6 inches long. The other sponge will need no wire, but an old tin or other plate will be well to hold it. Of course you will need your small bottle of alcohol. Let one stand on something that will allow him to hold the balloon well up from the ground. Wet the loose sponge with alcohol, not to drip, put in on the plate and set fire to it, holding the balloon over the flame so that the hot air will rise into and inflate it. As soon as the balloon will support itself the one who has held it by the top lets go and leaves it in charge of those below. One now wets the wired sponge with alcohol, quickly fastens its wire to the cross wires of the balloon, having it well away from the burning alcohol while doing it. As soon as secure, light the alcohol on the sponge on the balloon—hold on a second until you feel sure that it will go—then let her sail. It is very easy to do but it takes a long while to tell. In sending up a balloon, select a place where there can be no danger to barns or other buildings should it fail to go up, also a place where the halloon can not be caught by trees or otherwise before it gets above them.

**Picture Puzzle.**—How many faces are there here is a question that many will ask when they see this odd looking picture. Our artist sometimes gets a strange notion into his head, and don't you think this is a head of anything in the way of a combination of heads? The

chin of one face is the nose of another, and the nose of the other is the forehead of the one, and so on all around the picture. What a funny looking person he would be that had such a combination head. It might be good for a school teacher, as he could then look in all directions at once; and again, what a singing school such a head man would make!

Our Puzzle-Box.

ADOLPH M. NAGEL.

MIXED PROVERBS.

(In the following sentences are five well-known proverbs, displaced. Transpose the words and make the original proverbs: every word must be used.)

Where's the mother of brevity?

There's a time for wit and invention.

The soul is no light necessity.

Many a man will wait.

Hands make way! There's tide of work.

## DOUBLE ACROSTIC.

The initials name a well-known bird, and the finals, an animal.

1. An oriental tree.
2. A man's name.
3. An ingredient of plum cake.
4. One of the tortures of the Inquisition.
5. A fruit.
6. A country in Europe.

EFFIE.

## CHANGED HEADS.

(Change the first letter each time.)

1. First take a certain arrangement of rope; then change its head and make
2. Something very useful in carrying Saratoga trunks to the fourth story.
3. Again change the head and make something with out which
4. Would be of no use.
5. A person.
6. A bad thing to get into.
7. What every freeman has.
8. Compact.
9. A number.
10. "Good night."

## CROSS-WORD.

My first is in rampart but not in defence,  
My next is in income but not in expense,  
My third is in ocean but not in the sea,  
My fourth is in coffee but not in our tea;  
My fifth is in pitcher but not in the jug,  
My sixth is in tumbler but not in the mug,  
My seventh is in fragment but not in a rag,  
My eighth is in satellite but not in a bag,  
My ninth is in cricket but not in grasshopper;  
My whole is a mixture of zinc and of copper.

## PI.

Heret saw cone a codort, how, nhew saked thaw saw dogo rot quottessimo, tower cakh: "Who od ouy pupesso I nac lell sunsel I wonk thaw sail het quismoot?"

## NUMERICAL ENIGMAS.

1. I am composed of 28 letters:  
My 15, 20, 2, 3, 12, are certain birds.  
My 3, 8, 7, is a kind of sauce.  
My 16, 9, 2, is clamor.  
My 18, 25, 8, 4, 3, 27, 21, 28, is a number.  
My 11, 14, 15, is to dress.  
My 17, 19, 23, 21, 22, is a leather strap.  
My 13, 12, 1, 10, 17, 6, is abatement.  
My 5, 24, 11, 26, is scattered.  
My whole is very excellent advice. MARY A. E.
2. I am composed of 18 letters:  
My 13, 14, 9, 15, 5, 16, is a body of troops.  
My 17, 1, 8, 16, 4, 18, is a number.  
My 5, 6, 15, 3, 2, is an animal.  
My 12, 10, 7, 11, is to mend.  
My whole may be found on the map of Pennsylvania. JOHN M. M.

## TRANSPPOSED PROVERB.

(Readjust the letters to form the proverb.)  
He is bent to copy his style.

## METAGRAM.

In a word of five letters you may find three verbs, four nouns, two pronouns, a preposition, an adjective, an article, and an exclamation; among the nouns are a fish and a tree. What is the original word, and what are the different words formed from the five letters.

## ANSWERS TO PUZZLES IN THE MAY NUMBER.

CHARADES.—1. Dilemma. 2. Menhaden. 3. Driftwood.  
NUMERICAL ENIGMAS.—1. Honesty is the best policy. 2. The Lord is my Shepherd, I shall not want.  
ALPHABETICAL ARITHMETIC.—(1703)95482640(56067. (Key—Large Knobs.)

## DOUBLE ACROSTIC.

Sing—Song.

S—paciou—S

I—ntagli—O

X—ratio—X

G—an—G

ANAGRAMS.—1. Contumacious. 2. Asseverations. 3. Potentates. 4. Superscribed. 5. Validity. 6. Predetermined. 7. Archbishopric. 8. Fore-shadowing. 9. Metropolitan. 10. Greensward.

DECAPITATION.—Wheat, heat, eat.

CROSS-WORD.—Misfortune.

PI.—A remark of Patience Reville is at once lumpish, monitory and timely: "Respect the embarrassment of any honest conscience which doubts, which seeks, which likes better to rest in what is vague, and even to contradict itself, than to disfigure the unknown truth by giving it features fixed and perhaps unfaithful."

METAGRAMS.—1. Yawn. 2. Beryl. 3. Long. 4. Forty. 5. Home. 6. Villain. 7. Convex. 8. Alcohol. 9. Bread. 10. Clay.

ILLUSTRATED REBUS, 476.—Accumulate information and increase wisdom, but above all acquire integrity and honor.

No. 478. Illustrated Rebus.—Wholesome advice to every one and worthy of study here, and much practice every day.

## A Trip Over the Mountains.

The River Hunt, judging by the many letters from our readers, old as well as young, was a pleasant and perhaps an easy journey. With the warm weather upon us, it will be just the thing to change the direction of our rebus wanderings, and "take to the mountains," in the hope that a trip over some of them will refresh us in more ways than one. There has been quite an excitement over No. 1 of late years, especially among those men who are anxious to go into new mining regions

where it is hoped that a vast amount of gold and other precious metals can be found. Among these mountains (which, by the way, are not called mountains), the Indians have frequently made much trouble, so that at times the miners' lives were in danger. There are very few boys and girls in these mountains, and perhaps we had better hurry away before we meet with any mishaps. —Let us now take an imaginary flight, —suppose ourselves carried across the seas—to a foreign land, a peninsula, and a peculiarly-shaped one at that. These mountains (No. 2) are not of great height; the highest points being about 10,000 feet, or nearly two miles. None of the peaks of the range are covered with snow and ice the year round; there is here no point of perpetual snow, such as we may find before we reach home. Where these

mountains come near the coast of the great sea, their sides are remarkably high and steep. Two famous volcanoes belong to this range, about which volumes of interesting things have been written.—Leaving these mountains, and journeying by foot, or perhaps better, by rail, for a number of hundred miles, we will come to No. 3—a range which encloses a country like a great hoop, or semicircle rather, on its north and eastern boundary. One of the peaks is so high, and the region of these mountains so cold that there is a glacier or river of ice which runs—of course slowly—down the mountain side and melts in the warm valley below. These mountains are mostly clothed with woods for half the way up, after which are mostly rocks and snow and ice.—No. 4, from the name, ought to be 240 thousand miles away from the earth, but they are only a small part of that distance

from us. It is a considerable of a tramp to go to them, though, and they are in a land that is not very well known. It may be because they have been so little explored that they are named as they are. We can not be expected to be very familiar with mountains that no one else knows very much about.—No. 5 is a range that separates two great countries, which have been quite closely associated at certain times in the history of the two nations. The mountains consist of two distinct chains or ridges. The slope on the northern side is gradual, and covered with fine pastures, but on the south it is frequently very steep. Many parts of the mountains are of sufficient height to have their heads covered night and day and all the year round with white caps of ice and snow. There are as many as a hundred passes or places through which persons can go from one side of the mountains to the other—from the country on the north to the more sunny land on the south.—No. 6 runs almost parallel with a great river, and is situated in the central portion of a great country, the name of which is perhaps most familiar to young people—and old folks too—about Thanksgiving time. In going from the capitals of two large countries, a traveller would go through one of the few passes in this mountain range.—As we

return to that portion of the face of the earth—what a wrinkled face! Mother Earth must be very old—where most of our young readers live, we come across another range of mountains, and find our No. 7. There are a number of neighboring chains which run in much the same direction which we will not consider. A large river of the same name runs among these mountains, and afterwards flows into the longest river in the world.—No. 8. If we return to somewhere near where we started—at least the nearest to No. 1 since we left it to take a mountain tour of the world—we shall find a long and very dif-

SOME MOUNTAIN SCENERY NOT OFTEN SEEN ON THE MAPS.

ficult range to climb, but one which would bring us far into the upper air, because it contains some of the highest peaks in the world. But we can not stop to go the whole length of this chain, for we have one more, and that the most important in size that we have found. It is not far from where we started, and its name can be easily made out from the map which illustrates the subject. We hope that the hasty journey—flying trip we might call it—has not made you so tired on these warm July days, that you may not wish to go with us again.

## Something About Glass.

Some boy writes to "The Doctor," asking how window glass is made so flat and smooth "especially those in the large windows of store fronts." There are two kinds of window glass, one called "cylinder" and the other "plate" glass. All the large panes are plate-glass, as the size of cylinder glass cannot be increased beyond a certain point. In this kind of glass a cylinder is blown; those who have been in a glass house—and I advise all of you, whenever you have an opportunity to visit one and see how this wonderful material is worked—know that to make a cylinder, a globe is first blown. This is then worked into a cylinder, by rolling it upon an iron table; after the cylinder is made its ends are cut off, and it is divided lengthwise and flattened out to form a flat, smooth sheet. All plate glass is cast; a polished iron table has ledges at the sides, as high as the thickness of the plate of glass. The melted glass is poured upon this and spread and flattened by a copper roller. The plate is then annealed; that is, put into a very hot furnace, which is so arranged that the glass will cool very slowly, in order that it shall be tough when at the end of a week or so it is cool. But the glass is now dull and rough, like that which you see in roofs and sky-lights. To become the beautiful plate-glass it must be ground and polished. The plates are so arranged that they may be rubbed together, one upon the other, by machinery. First sand and water are placed between them, then emery of different sizes, and after being ground with the finest emery, they are polished by rubbing them for some time with some kind of polishing powder.

### The Day We Celebrate.

If there is any day in the year upon which the average Young American does not have to be instructed as to the time of its coming, that day is Fourth of July. The very air we breathe from the day we are born fills us with the spirit of the Independence Day. The coming "Fourth" reminds me of one in which I took an active part some years ago, and one, though without any striking events, that my memory has not allowed me to entirely forget. We knew it was coming, and when I say *we*, three young

that we all concluded to buy of Postmaster M.; first, because he had been a soldier and had lost one leg, and secondly, his stock of goods appeared to be the best. Our pyrotechnics (a pretty big word for fire-works), as fast as purchased, were by common consent stored in the loft in the barn. It may be that we had an idea that nobody knew anything about what was going on, and we wished to "keep things hid." This storing of fire-works in the hay in the barn is just the wrong thing to do, and if any young reader is led to do the same thing through my experience, I shall wish I had forever kept still on

small cannon and other fire arms. We had an audience at the window so soon as the exercises began. The firing was kept up until we concluded that the day had been well opened, and after taking a late and large breakfast we concluded to let matters rest until the heat of the day was over, and under the cover of darkness resume the exercises, as a better showing might then be made. Night came after we had had a day at fishing in the brook by the woods, where we had more bites from mosquitoes than anything else. The third scene gives an idea of how we finished up the day, and by the looks it

THE BOYS' "GLORIOUS FOURTH," AND WHAT IT BROUGHT FORTH.

farmer lads—no more and no less—are included. The almanac had been looked at more than once to see how time was progressing, and we fully agreed with it when it said all along through May and most of June that the days were getting longer. They seemed longer and longer even up to the very day of the celebration—and that opened early and closed late. What fun it is to get ready for any unusual "doings"; and when you add to it the happy thought that not a soul knows anything about it except the few companions of your choice, how full of real, solid, silent delight the little youthful heart must be. For this particular occasion we had come home early from school, and done extra work for weeks for the money we should get, or, to look beyond the cash, the sport that our toil would bring; all of us were glad to get an errand from any one who was "good pay"; and they all, as I look back now, understood the motives which led us to such an outward show of industry.

It was not later than the middle of June that we formed ourselves into an investigating committee on fire-works, and visited the neighboring village in a body. How we did look at those store windows where fire-crackers of all sizes and colors were displayed to catch the eye, and finally the pennies, of just such investigating committees as mentioned above. We bought our things at one time or another as the funds came in; but we were so patriotic

this point. Whatever you do, remember, as I did not, that barns are costly, hay is easy to set on fire, and fire-works are still easier to burn, and then the temptation is so great that some thoughtless boy may touch a match to that which will make a funny noise when it goes off.

The artist has helped me to show my nieces and nephews, how things looked the day before the Fourth when the Celebrators were gathered for the last time to look at the purchases, see that they were all there and in good shape, and also to make plans for the morrow which had been so slow in coming. This was the joy of anticipation, but with it was mingled that stillness that the time and place demanded. Of course we went to bed in much that fevered state of mind and body that thousands of boys all over the land will do this year; and passed as long and sleepless a night as boys always do on July 3d. The morning of the "4th" was a fine one; and the sun rose without a cloud—the first sunrise we had seen for some time. The second scene lets the young readers into the activities of the early morning, but of course it can not show the noise that was being made, or express the utter surprise of the dog to see us out so early in such a peculiar and excited state. It was not our intention to make a quiet day of it, and we started out accordingly. We broke the silence of the morning, and our secret planning for weeks was exposed, with loud reports of

might be supposed that the Celebrators were pretty well used up too. The hand that fired the overloaded cannon had been lamed, and was withdrawn from active service. The eye that had too closely watched the spattering and treacherous fuse had been dimmed, and was cut off from the outside world by a bandage, wet in cold water. But so sure as there is a "Fourth" there is a *fifth* to follow, and in our case it came altogether too soon. The fourth scene shows to some extent how we felt at that moment when a near relative called at our room to see what had become of the young hands that were accustomed to help him in the field during the morning hour before school. We looked tired, and we felt worse. The boy with the sore head, and the one with the lame arm, were the last to rise and the slowest to acknowledge that, after all, the Fourth of July was the hardest day that they had seen for just a year. As I look back to that morning, tired, sleepy, stiff and sore, I have to wonder at the seeming absurd way we, as American lads, show our love of country. Why is it that the young mind can not associate a more quiet time with "the day that our land was made free"? Whatever may be the truth of the case, the boys and girls will continue to celebrate the Fourth, and the dull, aching, Fifth will follow to remind them, as it did me, that the freedom the day allowed, leads into bondage, because I was bound with a towel. **UNCLE HAL.**

# NEEDLES

Male and Female Agents wanted to sell our FAMILY NEEDLE PACKAGE, containing 120 Large-eyed English Needles, as follows: Four papers, 25 in each, different sizes, also, two steel Bodkins, 3 Long Cotton Darners, 2 Short Cotton Darners, 2 extra fine Cotton Darners, 2 Wool, 2 Yarn, 1 Worsted, 1 Mottos, 2 Carpet, and 3 Shoe-Button Needles. The above are required in every family. Agents' Circulars free. Send 25c. in postage stamps for full sample package.

## DRY GOODS BY MAIL OR EXPRESS.

OUR MAIL ORDER DEPARTMENT is now so  
systematized, and in charge of such thoroughly competent  
and experienced hands, that persons unable to visit our  
store can do their shopping by writing us for samples or  
goods, with the assurance of getting them at the same  
prices as if buying in person. We carry an average stock  
of about half a million of dollars, all bought for prompt  
cash in the markets of Europe as well as in this country.  
Try us, and see how cheaply and quickly you can get  
what you want by mail or express. When in town we  
shall be pleased to have you call on us.

SEND FOR CATALOGUE OR SAMPLES.

COOPER & CONARD,  
IMPORTERS AND RETAILERS,  
Ninth and Market Streets,  
PHILADELPHIA.

Established 1852.

Mention this paper.

BEST IS CHEAPEST THOUGH IT MAY COST A LITTLE MORE!

## LEWIS' CONDENSED BAKING POWDER

Made from Refined Grape Cream of Tartar. Recommended by the Brooklyn (N. Y.)  
Board of Health, and by the first chemists in the United States. We will pay \$1000.00 for an ALUM  
or other adulteration found in this Powder. A pound can be mailed to any address on receipt of 60 cents.

Manufactured by G. T. LEWIS & MENZIES CO., Philadelphia.

## RIDGE'S for INFANTS FOOD AND INVALIDS

Has been manufactured in this country for ten years, and all orders for both the United States and  
Canada are filled by WOOLRICH & CO., whose name appears on every label. It is not, there-  
fore, an imported article. Its use, however, for 20 years in England and 10 years in America shows  
its standard worth. Ridge's Food is NOT a medicine, but a highly nutritious and because a  
COOKED FOOD, easily assimilated. Take no new untried preparation because offered at a  
cheap price, when Ridge's Food can be obtained from all Druggists at 35 cents and upwards.

## H.W. JOHNS' ASBESTOS

Liquid Paints, Roofing, Boiler Coverings,  
Steam Packing, Sheathings, Fire Proof Coatings,  
Cements, &c. SEND FOR DESCRIPTIVE PRICE LIST.

**POTATO BUG. COTTON WORM. CANKER WORM.**

**THE BEST  
INSECTICIDE  
EVER USED.**

**LONDON PURPLE.**

(Trade  
Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. It not obtainable of nearest dealer, send direct to sole manufacturers, **HEMINGWAY'S LONDON PURPLE COMPANY (Limited),** 60 Mark Lane, London, England. **90 Water Street, N. Y. P. O. address, Box 990.** A. H. WHITNEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have had the Canker Worm a long farewell, and have done it with your LONDON PURPLE. We put in about three-fourths to one pound of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

# POT CROWN Strawberry Plants.

All the new choice and standard kinds in large quantity, at very reasonable rates. Plants set in July produce a fine crop the following season. Descriptive Catalogue free to all applicants.

**CABBAGE PLANTS.**

Actually by the Million. All varieties. Prices, \$2.00 per M., \$8.50 per 5,000, \$15.00 per 10,000. Will have plants until first of August. Send for Price List. **G. R. CLARK, Scranton, Pa.**

As ye sow, so shall ye reap.

Fit all drill boots, run level, cut *flat* bottom furrows, cover with mellow soil, and instead of crowding the seed into narrow rows but one inch in width, scatter it 3, 4, and 5 inches; the plants thus standing wider apart, have more ROOM TO STOOLO, derive more nourishment from the soil, become more vigorous, and produce better developed average heads.

Send for Illustrated Circular with Testimonials to **J. A. JONES, Wilmington, Del.**

**Champion of the World!**

THE

**CHAMPION GRAIN DRILL**

With or without Fertilizer, or Grass Seeder Attachments, or Gum Spring Hoes.

# The "Centennial" Fanning Mill.

The best mill in the world. It separates Oats, Cockle, and all foul stuff from wheat. Is also a perfect cleaner of Flax, Timothy, Clover, and all kinds of seeds. The great improvement over other mills is that it has two shoes. It is especially adapted for warehouse use. Send for Descriptive Circular and Price List. Liberal discount to dealers. Address

S. FREEMAN & SON, Racine, Wis.

## HEEBNER'S IMPROVED Level Tread Railway Horse Power with Patent Speed Regulator.

Awarded the Medal at the Centennial, 1876.

Horses stand in the power with their feet in a natural position, relieving them of all strains and much of the fatigue occasioned by working on tread powers of the old style. Smooth shod horses or oxen work on them, walking at the rate of only 1 1/2 miles per hour. These Powers require less elevation, give more power, save the horses, and save money. Made with double or single gear, for one and two horses, and have the only successful Speed Regulator in the world.

### LITTLE GIANT THRESHER & CLEANER.

The simplest, most durable, best and easiest working, and cheapest machine for threshing and cleaning all kinds of grain, also flax, millet, clover, and timothy seeds now in use. It contains more good points than any other in use.

These Powers and Threshers are pronounced by all who use them to be, beyond a single doubt, the best in use. We own all the patents, and are the Sole Manufacturers, and have the machines in use all over the world. Send for illustrated catalogue. **HEEBNER & SONS,** Lansdale, Montgomery Co., Pa.

## Union Railway Horse Power.

### THRESHERS AND SEPARATORS.

These Powers are **GUARANTEED** to produce more Power with

**LESS ELEVATION** than any other Railway Power. Send for descriptive catalogue. **W. M. L. BOYER & BRO.,** 2301 Germantown Ave., Phila., Pa.

Also, manufacturers of the PREMIUM FARM GRIST MILL.

## CHICAGO SCREW PULVERIZER.

### Does Pulverization pay?

I seeded 3,400 acres of wheat with these machines... The stand of wheat is now the best I have ever seen on new land. **R. J. WEYMESS, Trustee.**

This year I harvested, on 190 acres, 6,100 bushels of wheat. ...In my opinion the Screw Pulverizer increased the crop one-third over what I could have got by any other method. **D. G. MOORE.**

Send for pamphlet with cuts, and over sixty letters from men who have the machine. Address,

## Chicago Scraper & Ditcher Co.,

34 METROPOLITAN BLOCK, CHICAGO, ILL.

### Bookwalter Engine.

Compact, Substantial, Economical, and Easily managed. Guaranteed to work well and give full power claimed. Engine and Boiler complete, including Governor, Pump, &c., at the low price of

3 Horse-Power...\$240.00

The Pitts Agricultural Works, Buffalo, N. Y., U. S. A.

## ORIGINAL AND ONLY GENUINE BUFFALO PITTS

**THE STANDARD** of Threshing-Machine excellence throughout the Grain-Growing World. **SELDOM EQUALLED.** Never excelled. **NOTORIOUS** as a fast yet thorough thresher, perfect cleaner, and entire saver of all kinds and conditions of grains and flax and timothy seeds. **NOTORIOUS** as the only machine that is a success in all kinds of threshing and a failure in none. **NOTORIOUS** as the best built, most durable, and handsomest of the Threshing-Machine Tribe. **STEAM THRESHERS** a specialty. Their superiority, it can be said with truth, is acknowledged throughout the world.

**CAUTION** To Agents as well as Threshermen. Be sure you get the genuine Buffalo Pitts, made only at THE PITTS AGRICULTURAL WORKS, Buffalo, N. Y. It is said that other manufacturers are using the name "Buffalo Pitts" on their make of Threshing Machines.

This Unintentional Compliment to the great reputation of the only genuine Buffalo Pitts, by use of its title to sell inferior machines, is flattering to the "Buffalo Pitts." But Agents and Threshermen must not be deceived, nor hold the genuine Buffalo Pitts responsible for the faults of its bastard namesakes. For Catalogues and Price-Lists of the genuine Buffalo Pitts, address

**THE PITTS AGRICULTURAL WORKS,** Buffalo, N. Y., U. S. A.

Spiral Spring Singletrees. Secured by two patents. Price \$3.50 per pair. Send for a pair, or send stamp for illustrated circular and full description. Local agents wanted. Territory for sale. **F. R. WILLSON & SONS, Columbus, Ohio.**

**Threshing Machinery and Portable  
and Traction Engines.**

**THE STANDARD** of excellence throughout the Grain-  
Raising World.

**MATCHLESS** for Grain-Saving, Time-Saving, Perfect  
Cleaning, Rapid and Thorough Work.

**INCOMPARABLE** in Quality of Material, Perfection  
of Parts, Thorough Workmanship, Elegant Finish, and  
Beauty of Model.

**MARVELOUS** for vastly superior work in all kinds of  
Grain, and universally known as the only successful Thresher  
in Flax, Timothy, Clover, and all other Seeds.

**ASTONISHINGLY DURABLE** and wonderfully simple, using less than one half the usual gears and belts.  
**PORTABLE, TRACTION, and STRAW-BURNING STEAM-ENGINES**, with special features of Power,  
Durability, Safety, Economy, and Beauty entirely unknown in other makes. Steam-Power Outfits and Steam-Power  
Separators a specialty. Four sizes of Separators, from 6 to 12 horse-power; also 2 styles Improved Mounted Horse-Powers,  
**52 Years of Prosperous and Continuous Business** by this house, without change of name, location, or manage-  
ment, furnishes a strong guarantee for superior goods and honorable dealing.

**CAUTION!** The wonderful success and popularity of  
our Vibrator Machinery has driven other  
machines to the wall; hence various makers are now attempt-  
ing to build and palm off inferior and mongrel imitations of  
our famous goods.

**BE NOT DECEIVED**

by such experimental and worthless machinery. If you buy  
at all, get the "ORIGINAL" and the "GENUINE"  
from us.

For full particulars call on our dealers, or write  
to us for Illustrated Circulars, which we mail free. Address  
**NICHOLS, SHEPARD & CO., Battle Creek, Mich.**

**FRENTRESS.****Steel Wire  
Barb Fence**

Patented Dec. 14, 1875.

Re-issued May 2, 1877.

**The Best and Most Durable  
of All Barb Wire in Use.**

A sure protection, cheaper than board or rail fence, and good for a life-time. Wastes no ground. Has no weedy fence-  
row. When the best costs no more than an inferior article, always look for the best. We claim for the **Frentress** a  
**Superiority over all other Wires.** For Circulars and Price Lists address

**ST. LOUIS WIRE FENCE CO.,  
814 & 816 N. 2d St., St. Louis, Mo.**

**FRENTRESS BARB WIRE FENCE CO.,  
East Dubuque, Ill.**

**Kelly Steel Barb Wire.**

**IS FREE FROM LITIGATION.**

Patented in 1868, and licensed under all first Patents.

**A FENCE FOR A LIFETIME.**

**Has No Superior, and Admits No Equal.**

The Kelly diamond-shape **Steel Barb** is placed on the wire without loss of metal, leaves no room for moisture to  
rust the wire, retains its sharp points, and saves fully 10 per. cent in weight per rod.

**BUY NO OTHER.**

If your Merchant don't keep it, send direct to Manufacturers. Send for Catalogue.

**THORN WIRE HEDGE COMPANY,  
CHICAGO, ILL.**

**THE LATEST IMPROVEMENT IN BARB FENCE.**

The cut shows exact size of strand and distance apart of barbs. Not dangerous to horses or stock. Price the same by  
the pound or rod. **SAMPLES SENT FREE TO ANY ADDRESS.**  
**AMERICAN BARB FENCE CO., 60 Clark St., Chicago, Ills.**

**IMPROVED BAY STATE RAKE.**

This Rake Received  
the Highest Award at the  
Centennial Exposition  
and Field Trial. The  
only Silver Medal awarded  
at the Paris Universal  
Exposition, in 1878.

This rake has taken  
more first premiums than  
any other rake.

It is Easily Handled by  
a Girl or Boy, strong  
enough to drive a horse.

An Illustrated Catalogue of all our Tools and Implements  
sent free.

## COLUMBIA BICYCLE.

Bicycle riding is unsurpassed as a method of travelling, whether for speed, sport, or the renewal of health. No horse can compare with the bicycle for endurance, no other pastime is half so fascinating, and the exercise is recommended by the medical profession as being most conducive to health. Appleyard rode 100 miles in 7 hours, over a common turnpike road, and Waller has accomplished 1,400 miles in 6 days. Send 3c. stamp for 24-page catalogue, containing price lists and full information, or 10c. for catalogue and copy of "The Cycling World."

THE POPE MFG CO.,  
No. 101 Summer St.,  
Boston, Mass.

## SEND FOR ILLUSTRATED PRICE LIST OF PRESSES, DIES AND OTHER FRUIT-CAN TOOLS.

FERRACUTE MACHINE WORKS,  
Bridgeton, N. Jersey.

## WELL BORING,

ARTESIAN WELL DRILLING & MINERAL PROSPECTING MACHINERY. and how to use, is fully illustrated, explained and highly recommended by the "American Agriculturist" in the November Number 1879. Page 465. Send for it. Portable, low priced, worked by hand, horse or steam power. Needed by farmers in every county. Good business for Winter or Summer, and very profitable. Can get good wells in earth or rock anywhere. We want the names of men that need wells. Send for illustrated price-list and terms to Agents. Address, "Well Excavator Co., 29 Ross Street, New York, U. S. A."

Grind your bone meal, crush your own oyster shells in the \$4.00 Hand Mill. Samples 6 cts. Larger sizes for farmers—to run by power. Testimonials furnished.  
FRANK WILSON, 52 Delaware St., Easton, Pa.

## C. GILBERT'S STARCH

## Muth's All Metal Honey Extractor, And Uncapping Knife.

Have received the Highest Encomiums!—Also Langstroth's Bee Hives; Honey Jars, and a full assortment of Bee-Keepers' Supplies. Every Bee-keeper should send for my circular giving the details regarding the Care of Bees and How to get the most Honey. Sent free on application.  
CHAS. F. MUTH, No. 976 Central Ave., Cincinnati, O.

## FRIENDS! If you are in any way interested in BEES OR HONEY,

We will with pleasure send you a sample copy of our MONTHLY GLEANINGS in BEE CULTURE, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Artificial Comb, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. Nothing Patented. Simply send your address on a postal card, written plainly, to  
A. I. ROOT, Medina, Ohio.

**AGENTS WANTED EVERYWHERE** to sell the best Family Knitting Machine ever invented. Will knit a pair of stockings, with HEEL and TOE complete, in 20 minutes. It will also knit a great variety of fancy work for which there is always a ready market. Send for circular and terms to THE TWOMBLY KNITTING MACHINE CO., 409 Washington St., Boston, Mass.

Are sold by all Hardware and Harness Dealers. There is no one owning a horse or mule but what will find in this line of goods, something of great value, and especially adapted to their wants. COVERT MFG CO., West Troy, N. Y., Sole Manufacturers.

## THE BAKER GUNS.

We make the best double gun in the world for the money—choke-bore, rebounding locks, extension rib. Our \$40 gun has the best English twist barrels, and the best material throughout. All guns sent on trial and guaranteed. Price—Best English Twist Barrels, \$40. Damascus steel, \$55 to \$200. Send stamp for Descriptive Circular.

**Creameries on Trial.**—The manufacturers of The Ferguson Bureau Creamery, announce that they will send out their Creameries on trial.

This apparatus has given such universal satisfaction for the last three years, and they have such confidence in its perfect adaptation to the wants of all dairymen, that they freely offer to send one to any reliable party, of such size as they need, on 30 days' trial. If it does not work satisfactorily it may be returned.

In the last year they have sent out over two hundred Creameries on these terms, and NOT ONE has been rejected.

Particular attention is called to the fact that the Creamery can be used with either ice, running spring water, or cold well water, and that it is especially useful in cold weather. After a person becomes accustomed to it, they will be able to use it nearly the whole year without artificial cooling, by taking advantage of the cool night air, according to the directions.

No other Creamery is offered on such liberal terms, and no dairymen in justice to himself, and to his wife (for they are especially adapted to dairies where women do the work), should buy any apparatus until he has given the Bureau Creamery a trial.

They also offer to send their Concussion Churn on the same terms.

Messrs. Wells, Richardson & Co., the well known manufacturers of the Perfected Butter Color, are largely interested in the Ferguson Manufacturing Company, and we have their guaranty that all the business of the Company will be done in the most honorable manner.

We advise all our readers in want of milk setting apparatus to correspond with the Ferguson Manf'g Co., Burlington, Vt.

### TESTIMONIALS.

CORNWALL, VT., May 21, 1880.

THE FERGUSON MANF'G CO.—Gentlemen: You ask for my experience with the Bureau. We have used one for the last two years, and so far this.

We are perfectly satisfied with it, and are sure that it is the best method of setting milk, giving all the cream, and with the least labor in taking care of the milk.

There are two in this vicinity, that are saving to those using them the expense of a hired girl—the ladies finding that the Bureau saves them so much work in skimming and washing small pans, that they can now do their own work alone easier than with help before.

We find that we do not have to use ice except in the very hottest weather; if we will take care to open the Bureau in the evening, so as to use the cool night air, and shut the Bureau in the morning, it will keep cool all day.

One day this week, when the thermometer was among the eighties, the milk in the pan that I emptied at night was 62° by the thermometer, and that without any ice, showing how easily we can keep the milk cool by just using the night air. We have not put any ice in our Bureau yet this year.

To any one wishing the Easiest, Neatest, Quickest and most Perfect method of setting milk, we would recommend the Ferguson Bureau Creamery.

Respectfully, WM. H. MATTHEWS.

"I have used the Ferguson Bureau Creamery, and in my opinion it is the best cream-raising apparatus with which I am acquainted.

"I find it to produce the largest amount of Butter, and of the best quality, and with the greatest saving of labor. I prefer it to any deep-setting apparatus, or any open pans, and cheerfully recommend it to all dairymen."

May 22d, 1880. CHAS. E. FISKE, Greenfield, Mass.

[Mr. Fiske made the butter that took Five First Sweepstakes Prizes at the Mass. Butter Show last December, (the Mass. Sweepstakes, \$50; the New Eng. Sweepstakes—a Mosely & Stoddard Creamery; the Ferguson Sweepstakes—a Bureau Creamery; the Franklin Co. do. —\$12; the Boston dealers' do.—\$10.]

## AMERICUS CIDER MILL

### WHITMAN'S PATENT.

The Best Cider and Wine Mill made. It will make Twenty per cent more Cider than any other.

Perfectly Adjustable.

### Three Sizes.

Geared outside. Large Mills made for two cranks. Prices as low as any first-class mills.

Circulars giving full description sent free. Address the manufacturers.

WHITMAN AGRICULTURAL COMPANY,  
Saint Louis, Mo.

## Three-Barrel Two Shot and GUN. One Rifle.

A new feature in the Gun line. It is light, compact; from 8 to 10 lbs. in weight. The Rifle is perfectly accurate. It has proved a great success for all kinds of shooting. All guns shipped on trial and guaranteed. Price \$75 to \$250.  
L. C. SMITH, Sole Maker of Baker Guns, Syracuse, N. Y.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 260.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the *American Agriculturist* are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members. or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist* (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Order, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Bitter Milk.**—Last month we gave the statement of Mrs. "A. N." of Texas, that the milk was made bitter by Dog-Fennel, which the cows ate. Prof. D. L. Phares, Woodville, Miss., writes that it is a common error to suppose that cows eat the plant named. He says "Cows do not eat Dog Fennel, nor if eaten would it produce the alleged effect. The plant producing the bitter milk is *Helenium tenuifolium*—Bitter-weed. Where this plant is eaten in large quantities it causes the butter to be a little bitter and also the flesh. Mutton is rendered bitter by this same plant; and cooking does not remove the bitterness. Ignorance of these facts caused families to suppose that attempts were made by servants to poison them. And it has been my fortune more than once, by showing the true state of the case, to save innocent persons from prosecution for 'attempt to poison.'" The plant in question is a native of the Southernmost States, and is sometimes seen in northern gardens. It has smaller yellow flowers than the common *Helenium autumnale*, the "Sneezewort" and very narrow, almost thread-like leaves.

**Excursions to Europe.**—When one has determined to make a visit to Europe for the first time, his first step in the way of preparation is to look up some friend who has already been there, and inquire of him as to routes, hotels, expenses, and such other particulars as will help him on the way. Every one can not readily find a person who can give him such aid, but he can procure it of Cook & Son, the excursionists, who have a wide reputation for taking excursion parties to nearly all parts of the world. It is not necessary to travel with a party in order to avail one's self of Cooks' facilities, as a large part of their business is in furnishing tickets and information to single travellers and families.

## A Perpetual Source of Interest, and Instruction,

To every Family, and to every individual, is a really good **Compound Microscope**, which is a far more effective and satisfactory instrument than anything in the way of a Simple Microscope. The latter, by means of a single lens, or two or three of them placed together, simply magnifies objects from 3 to 25 diameters, though not very distinctly above 10 or 12 diameters. The Compound Microscope makes a magnified *image* of the thing looked at, while other lenses remagnify this image, and thus the original object is seen enlarged a hundred or a thousand or more diameters, and many thousand times its original size, according to the power of the instrument. Then it has sundry arrangements for adjusting the focus, for holding the object, for concentrating light upon it, etc., etc. The Microscope opens a new world to one far more extensive, and if possible more interesting than anything that can be seen with the unaided eye. For example, the fine dust on the wing of a butterfly, or moth, seen under the Compound Microscope, becomes a mass of most beautiful feather-scales of regular form and construction. The foot of a fly, or other insect, becomes an object of great interest. The mould upon cheese, or on leather, etc., appears as a minute forest of plants, as it really is. There is a vast number of objects all around us that can thus be exhibited to the eye in most wonderful forms, and the instrument is a perpetual source of interest, instruction, and wonder.

Until recently, a really valuable Compound Microscope, with all its parts, has been far too costly to be within reach of most families or individuals. After long effort, repeated trials, and many failures, the Editors of the *American Agriculturist* succeeded in securing a Compound Microscope having all the parts and the effectiveness of those costing five to ten times as much money, so that this most desirable instrument is now brought within reach of the great mass of the people. This most desirable end has been reached not only by new devices and inventions, but especially by the application of automatic machinery to making with great accuracy the multitude of parts that were previously only made by slow and less accurate hand-work.—A large number of these new Compound Microscopes have been made and tried, and strongly approved not only by the highest scientific authorities, but by many unscientific families who have put them to practical and most interesting use, so that we can now recommend it to all with entire confidence that it will give the highest satisfaction and delight, not only to the young and old of all classes, but to Schools, to Physicians, and to scientific investigators.

A marked feature of this new Instrument is the **Camera Lucida**, which enables one to throw the greatly magnified image of any small object upon paper in such a way that it can be readily drawn or sketched for preservation, even by a child large enough to hold and use a pencil.

A full Description of the Instrument, with engravings, showing its parts and use, etc., will be forwarded to any one desiring a copy, upon receipt of address.

**How Much Corn for a Hen.**—"G. B. T." Owego, N. Y. One bushel of corn will feed one hen for one year, and if she has the run of a barn yard and the fields, she will do well on this quantity. If given no other kind of feed, a hen will need a quarter of a pint of grain a day, or 45 quarts for the whole year.

**Sit or Set?**—"S." No, either is not right. You set a hen, but the hen's business is to sit. The hen lays eggs, and the eggs lie in the nest. There is a difference.

**Moving Westward.**—If we should draw a north and south line through the United States, dividing the country into two parts, so that there would be the same number of bushels of wheat produced on the west side of the line as on the east, it would be found that the line each year would have to be drawn farther westward. According to the report of the Bureau of Statistics, this westward movement of the dividing line has been on an average nearly 15½ miles for each of the last 28 years, or upwards of 450 miles in the last 30 years. If an east and west dividing line is drawn it will be

found to coincide nearly with the 40th parallel. The central point of wheat production is then moving to the west along this east and west line; it was in Eastern Ohio in 1849; ten years later in Indiana; a decade later in Eastern Illinois, and now the hub, so to speak, is in Western Illinois, but will soon cross the Mississippi.

**To Destroy Chinch Bugs.**—"T. H. G." Whiteside Co., Ill. Chinch Bugs may be destroyed in great numbers, by burning the stubbles and rubbish, or by plowing it under, when many will find their way to the surface again. Burning makes an end of them.

**"Seeding Down" With Roots.**—"L. A. J." Plymouth Co., Mass. This is always summer or fall seeding, and is done after the cultivation of the roots is over. The practice is most usual in connection with such roots as may be harvested without much disturbance of the ground; but it is not particularly objectionable to seed down with Carrots, Sugar-beets, or such Mangels as have to be started with a spade, or fork, at harvesting. It is important that the ground should be left nearly level at the last hoeing, to rake or hoe in the seed, and to roll after the roots are pulled.

**Ash of the Pea-Nut.**—II B. Cornwall, Prof. of Analytical Chemistry in the John C. Green School of Science, College of New Jersey, Princeton, having occasion to refer to the composition of the Pea-Nut, could find no analysis of the ash. This deficiency was supplied by Mr. W. M. Norris, a post graduate student at the School; the results of the analysis, now for the first time published, are forwarded by Prof. C.

Per 100 parts of Ash ;	
Silica.....	1.08
Potash.....	44.73
Soda.....	14.60
Lime.....	1.71
Carbonic Acid and Carbon undetermined.	0.15
Magnesia.....	12.65
Phosphoric Acid.....	17.64
Sulphuric Acid.....	2.53
Chlorine.....	0.15

The kernels yielded 2.03 per cent of ash.

**Spent Tan Bark.**—"W. A." McVeytown, Pa. Tan bark is of no use as a fertilizer, except for the ash it contains. The best use to make of it is to employ it as a mulch around young trees, errant bushes, etc.

**To Break Up a Broody Hen.**—"J. S." Baltimore, Md., gives his method thus: "You inclose the hen in a coop (light or dark), and keep her there for 3 days and 3 nights. She must not have a particle of victuals or drink. When she emerges she will be so 'run mad' hungry, as to banish all thoughts of her former intentions. No fear of starvation in this plan. I have practised it for years, and recommended it to hundreds. It is a sovereign cure. Several hens may be put together. One obstinate case in 100 may occur. Then repeat the dose."—But how about the Society for the Prevention of Cruelty to Animals, and its good work?

**The Boys' Cotton Crop.**—The "Alabama Farm Journal" has offered a premium of \$50 to the Alabama boy who shall raise the largest crop of cotton on a half-acre of land. We hope there will be a large number of young cotton growers that will enter their names for this prize; of course only one out of the hundreds who try can get the prize, but the trying will do every one much good. Other States might offer prizes for different crops.

**Some Dairy Figures.**—The dairy industry in the United States represents over \$1,300,000,000, with an annual production of \$350,000,000 worth of Butter and Cheese. This is \$50,000,000 more than the wheat crop of the country. The number of pounds of butter made last year, as near as can be calculated, was 1,500,000,000 pounds.

**Fish Skins.**—It is comparatively recent that fish skins have been put to any practical uses. At Gloucester shoes have been made from the skin of the Gusk, and a patent is said to have been secured for this preparation. The skins of thornbacks are prepared as a substitute for sandpaper. Bouquets of flowers are also made from them.

**The English Sewage Farms.**—"M. W. S." LaSalle Co., Ill. The sewage farms in England have not been profitable ventures directly. Indirectly they have saved money for the towns and cities, inasmuch as the cost of running the farms has been less than that of disposing of the sewage in the ordinary way, considering cost in its fullest sense and not in its pecuniary meaning wholly. Every dollar's worth of product grown on the farms has cost probably two dollars, but the waste has been got rid of very cheaply and inoffensively. Reports of the different sewage farms have been published in various English journals, but we do not remember that there has been any publication in a more permanent form.

**T. N. S. S. F. T. P. O. C. A.**—What a pity that so good a thing should have such a name that its initials only make the formidable array of letters above given. "The Nova Scotia Society for the Prevention of

Cruelty to Animals" sends us a circular by its Secretary, John Naylor, Esq., in which they announce to kindred Societies, and to all interested, that they have examined a new cattle car, which they recommend to other Societies and to railroads generally. To read the description of the excellent arrangements for the comfort of the animals, one wishes that the inventor would turn his attention to the construction of cars for carrying passengers.

**A Doctor on Pie.**—Here is a man, and a doctor too, that has no sympathy for the much abused pie. "Pie is vile, because it is indigestible, inexcusable, and mysterious. It is indigestible from the very nature of its composition, it is inexcusable because it is tampering with the holiest functions of the stomach to offer pie to it in place of food, and it is mysterious because you don't know what you are eating."—There are two general classes of pie, the one we eat and think well of it, the other—well! it is the kind the doctor has described.

## Cabbage Worms Again—Other Remedies.

The Cabbage Caterpillar or "Worm," has so many natural enemies, that these, aided by the means for its destruction employed by the owner of the cabbages—man—have so greatly reduced its numbers that we now hear but little of it in localities where, a few years ago, it was feared that cabbage culture must be abandoned. In those places where it appears for the first time, cultivators are having the same experience that those of us had who endured the visitation when the insect first appeared in this country a dozen or so years ago. It happens that the Cabbage Worm is a matter of great importance in some parts of the country every year, and whatever relates to its destruction is of interest to a large number of readers. We gave, last month, some hints about destroying the worms in advance, so to speak, by killing the moths before they can lay their eggs. We also stated there, that the most generally successful remedy is hot water. To many, the idea of applying hot water to a living plant is new, and such persons ask for more full directions. Like the hunter who aimed to kill if the animal should be a deer, but to miss if it were a calf, we must have the water hot enough to kill the worm and miss the plant. This is 160°, or from that to 170°. One with a little practice, after learning how water heated between 160° and 170° feels to the hand, hits the right temperature without the use of the thermometer every time. The water is conveniently applied with a common watering-pot, but that is ordinarily made with a rose, which scatters too much, and there is a waste of water, a matter of no little consequence if one has to bring it a long distance. If many plants are to be treated, it will pay to have a rose made for the purpose, one much smaller than those sold with the pot. It should be borne in mind that the water, in passing through the air in small streams, will cool rapidly. Matters should be so managed that the water shall be at the temperature named when it reaches the worm. The water in the pot may be considerably hotter than 170°, and if need be, cooled by holding the rose at some distance above the plant. On the other hand, if the water is scarcely above 170°, the rose, in applying it, should be held close to the plant, to avoid cooling. Those who put a little thought into their work will have no difficulty.

A correspondent, "G. M. L.," Cincinnati, O., writes that Wheat Bran, or Shorts, if sprinkled upon the cabbages when they are wet with dew, or rain, will completely banish the pests. When the Cabbage Caterpillar first made its appearance we gave all the remedies in use in Europe, where it is an old trouble, and Bran among the others. Since then, having heard nothing of its use, we had forgotten about it until reminded by our correspondent. We suppose the bran, in this case, acts mechanically rather than as a poison; the particles of bran probably irritate or otherwise annoy the worm and interfere with its movements, and the insect starts off in search of more comfortable feeding grounds.

Among other things used in Europe to get rid of these caterpillars is the common Brake, or Bracken, a tall coarse fern (*Pteris aquilina*), found almost everywhere. The fronds (leaves) of this are laid upon the cabbages, and the worms are said to leave at once. The leaves of the Elder are used for the same purpose; our Elder is quite different from the European, and may not have the same effect, but it is easily tried. In France the refuse from the Hemp brakes, the broken leaves and crushed seed pods, is used. The odor of this is said to kill the worm in a very short time. It has been suggested to sow Hemp seeds between the cabbage rows that its odor may keep off the insect. A year or two ago we published the statement that some European gardener had discovered that water, in which the clippings of Tomatoplants had been steeped, promptly killed plant lice and other insects. We would suggest a trial of this upon the Cabbage Worm. While we have no doubt of the efficacy of hot water, a cold application is attended with much less trouble, and for that reason preferable.

## Bee Notes for July.

BY L. C. ROOT.

It is safe to say that the greater part of the best surplus honey is, in most northern localities, gathered from Basswood. The bloom commences in Central New York from the 10th to the 20th of this month; the present season it may begin even earlier than this. The yield continues from 12 to 20 days, according to the variation in the opening of the flowers, caused by the difference in altitude and other local causes. Basswood is a free bloomer, and generally yields honey profusely, and of superior quality; in fact, I think basswood honey is not surpassed by that of any other plant in any region of the United States. I speak of this to show the necessity of having all things in readiness, to take the advantage of this most valuable honey yield when it comes. The practical bee-keeper has been preparing for this harvest for many weeks. Strong stocks, and plenty of room for storing surplus honey are the essentials. Every bee-keeper should be familiar with the sources from which he is to expect his honey, and be fully prepared to secure it promptly. If a day is lost, no after vigilance will secure the honey which might have been obtained during

A TWO-STORY HIVE.

that day. Many bee-keepers wait until the yield has begun, before they prepare their boxes, or arrange their swarms for surplus, and they are the ones who find the keeping of bees the least profitable. The basswood blossom matures very slowly. In riding through the country for the past week, I have looked for the first appearance of the buds, I find the trees heavily budded, at this date, May 29th. They are nearly one half the size they will attain when open, and yet they will not be in bloom until the first half of July. The old saying that "good things come slowly" is applicable here. They seem to start thus early, and mature slowly, to keep us in mind of the good yield coming, and to give us ample time to be fully ready. Let us then have our boxes ready with generous starters of natural comb, or comb foundation, and properly arranged at as early a date as the bees will begin filling them—or if the surplus is to be taken in the form of extracted honey, have the empty combs in place which are to be used for this purpose. There are two methods of doing this: many bee-keepers prefer placing one hive above the other, as shown in the engraving. Others advocate a brood hive where the extra combs are added at the side of the brood combs. Our preference has been to place these combs at the sides rather than the top. We shall test the two methods extensively the present season, and give the results at a future time. If it is the intention to extract the honey, procure an Extractor in season, and have casks or cans in readiness for storing the product. I speak of basswood at this time because of its value in most locations. The same advice is applicable to any class of blossoms from which the yield of honey may be expected. Be ready for the yield from whatever source it may come.

**Ice and Ice-Houses.**—In these hot July days, we would call the attention of those who did not build and fill an ice-house, as advised last winter, to the comfort, convenience, and money value of a good supply of ice at this season of the year. Perhaps this reminder will stir some persons up to the resolution to build and fill a house the coming winter, at least it is hoped so.

**American Apples Abroad.**—The extent to which our apples find a market in Europe is surprising. It is impossible to give any exact figures on this article of export, but when a single firm shipped 30,000 barrels in 1879—a poor apple year—we may conclude that our

standard fruit is in demand; and that the best varieties—those of fine quality, and good keepers—will find a ready foreign sale. It is reasonable to expect that the close of the present year will see the export of apples well up among the millions of barrels. With this expectation, it is well for orchardists to see that a good share of their fruit is of a kind that will bear the ocean transit, and also be acceptable to the eye and palate of the foreign consumer. The Baldwin, Newtown Pippin, Spitzenberg, Northern Spy, and Roxbury Russet are among the foremost of the varieties that are in most demand abroad.

**Small Fruits.**—This is the season of small fruits, and we wish every family throughout the country had all of them that they could use. A noted writer has recently said: "Small Fruits, to people who live in the country, are like heaven—objects of universal desire, and very general neglect." There is more solid truth than comfort in the above remark that is so strongly put.

**Drawing Grain, etc.**—If there is only one team upon the farm, and two wagons are to be had, it is often a great saving of time to change the team from one wagon to the other, so that there may be a wagon in the field loading and another in the barn being unloaded at the same time. In this way there may be no going of the hands to and from the field, except the one who handles the team. Three wagons and two teams are still better.

**Fix Up the Barn.**—When we go along the country highway, and see the wide cracks in the empty barns, we want to stop and tell the owner that those cracks are leak holes in his farm management. Through these places the farmer's profits slip away, because the thief—cold—finds here its entrance. While his cattle shiver, some fodder must pay the cost, or less flesh and milk are the results. Now, before another winter, stop the leaks.

**Results of Ensilage.**—Dr. John M. Bailey, of "Winning Farm," near Bellerica, Mass., is pleased with his results of Ensilage. He says: "Since the opening of my silos, Dec. 2, 1879, I have been feeding a large stock of cattle and sheep upon corn fodder, ensilaged last Sept. I am now (May 1), feeding my milch cows, and ewes and lambs upon it exclusively. Its preservation is as perfect as when the silos was first opened." Dr. Bailey cordially invites farmers to visit his silo, and inspect the system of preserving green fodder, which he prizes so highly.

**Cow Milkers.**—There are still inquiries regarding "milking machines" now and then coming to us, and this of itself shows that many are at least slow to accept them as proper instruments in the dairy. There are cases when tubes of some sort are necessary to draw the milk from the udder, as, for example, when the teats are badly chapped, the udder eaked, or when the cow is a very hard milker. Under ordinary circumstances the old way is the safest and best, and if nothing is the matter with the cow we should not encourage the use of any of the milking tubes or so-called "milking machines."

**The Buckwheat Field** usually receives the poorest attention of any farm crop, and sometimes the preparation given the soil—usually the least fertile portion of the farm—is so imperfect, that it seems like imposing on the good nature of this plant to sow it and expect it to grow at all. But the buckwheat plant can stand this harsh treatment better than any other grain, and for this reason it is so valuable in building up a worn-out, or otherwise poor soil. It should be borne in mind that if buckwheat will improve a field when poorly treated, it will do all the more good if the soil is thoroughly prepared for it, that a good bed may be given the seed to grow and do its best. If it is intended to plow under the crop as a green manure, then an application of a quick acting fertilizer will pay well, that a large growth may be secured to be turned under.

**Coal Ashes for Walks.**—Coal ashes are of very little value as a fertilizer, and are not worth applying to the soil unless they will make it lighter and loose, and thus improve it mechanically. After trying all sorts of materials, a writer in "The Garden" (London) says he finds none better for walks than coal ashes. The bottom of the walk is made of stones and coarse pebbles, covered with an even surface of the ashes, which, when thoroughly rolled down, makes one of the most pleasant of walks, and is easily kept free from weeds, and smooth and compact. This agrees with our own experience.

## The Auction Sale of Jerseys.

The public sale of Jersey cattle in charge of Peter C. Kellogg & Co., held in New York City on May 26-27, was in some respects an interesting and noted one. It afforded a striking illustration of the importance which is now attached to animals that have a blood relationship with those that are or have been great performers at the pail. The reputation which the cow "Alpheia" obtained as a butter producer, attaches itself to all animals that have the blood of that famous cow or that of her own brother, "Jupiter," in their veins. A portrait of "Alpheia" was given in the *American Agriculturist* in May last, where will be found an account of her great butter-making qualities. We did not at that time think we should so soon have an illustration of the great value that attaches to such an animal in her progeny. The descendants of "Alpheia" and "Jupiter" will sustain the reputation of the mother of the "Alpheia" strain" of Jersey cattle, and it is because these qualities are perpetuated, that so much importance is attached to the nearness of a given cow to another that has been a remarkable milker. For example—"Enrotas," the most famous Jersey cow now living, is a granddaughter of "Alpheia," and there are others that are, so to speak, "chips from the same block." It is not surprising that those animals at the sale, which had more or less of this valuable "Alpheia" strain, were eagerly sought for, and the prices at which they sold were high. A son of "Enrotas" headed the list—a calf "Ramapo" of 7 months—and was struck off to Mr. Lawson Valentine, of New York, for \$600. This was a surprisingly low figure, and an offer of \$1,000 was shortly refused by the purchaser. This handsome animal is now at Houghton Farm, Orange Co., N. Y., where it is expected he will develop into a breeding animal that will sustain the reputation of his family and worthy of the distinguished company in which he will find himself in the Houghton Farm herd. The two cows having the largest proportion of "Alpheia" blood, namely, "Myra 2d" and "Lass Edith," were highly appreciated by a number of cattle men, and the bidding was spirited and enthusiastic. Both were purchased by Mr. Valentine at the following figures: "Myra 2d" (6289), at \$1,400; "Lass Edith" (6290), at \$1,425. The mingling of the "Alpheia" blood in these valuable cows, and also the relationship which they bear to each other, can best be shown by the combined pedigree chart which is here given. It is interesting to note that the two heifer calves of these cows sold at the same sale at the following figures: "Lass Edith 2d," \$825, to Moulton Bros., and "Donnabel," daughter of "Myra 2d," sold for \$810, to J. Stillman. "Butter Boy," the sire of these valuable young heifers, was also secured by Mr. Valentine. It is a matter of congratulation that the animals of the "Alpheia" strain were not widely scattered in the public sale, but were kept together as the foundation of a Jersey herd at Houghton Farm, which, under the supervision of Prof. Manly Miles, Mr. Valentine can reasonably hope to make of national reputation. The sale of the second day consisted largely of unregistered and grade animals, and was in marked contrast with that of the previous day, in the character of the animals and the prices at which they were sold, and the two days afford a striking illustration

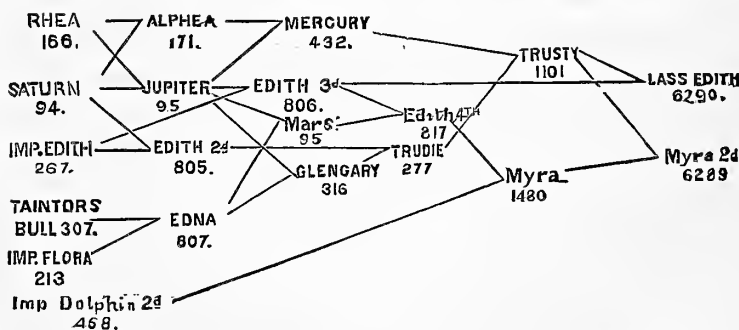

DIAGRAM OF PEDIGREES OF "LASS EDITH" AND "MYRA 2D."

of the real money value of a noted pedigree. If some of our readers consider the prices paid for the cows and heifers as "fancy," and extravagantly high, we have only to say that the animals sold for what a company of shrewd and intelligent breeders considered them worth, and they were the result of sharp competition among men who are not given to paying more for things than they are really worth. The prices would indeed be "fancy" as the value of these as butter-making cows and heifers, but with them was bought the possibility of a long line of descendants, each of which can claim a share of "Alpheia" blood. How valuable this blood is, the sale of the second day shows. Here good animals were offered, but they could not only not trace back to a strain of "Alpheia" blood, but could not trace back at all, having no record. As a consequence, sixty-two cows, some of them excellent milkers, sold at an average of about \$50 per head.

**Winter Fodder—Still a Chance.**—The grass in many places has been destroyed by the Army Worm, in many other cases a short hay crop is due to the drouth. But farmers can still sow fodder corn with a fair prospect of a good crop. This can be cured in the usual way, or stored fresh in silos. Though we have already given a full account of the process of *ensilage*, we shall describe it again in time for those who wish to do so, to make a trial of it. It is sufficient to say in this last word, as we close the pages, that there is no real cause for any one to despond. The great national plant, Indian Corn, now comes to the rescue. Early and prompt action—as abundance of manure, if green and fresh, no matter, a quick growing kind of corn, and sowing at once, will, in all ordinary seasons, give an abundant crop, of the best possible fodder. Do not lose a day, but sow the corn.

**Canoe and Camera.**—A Two Hundred Mile Tour through the Maine Forests, by Thomas Sedgwick Steele. New York: Orange Judd Company. This work will be appreciated by two classes of persons: those who go to the Maine forests, and those who do not. It is not many years since the "back woods of Maine" were quite unknown to any save lumbermen, but of late, as their attractions became known, they have been penetrated by tourists, each year bringing increased numbers. To those who contemplate a visit to this little explored country, this work will be most valuable, as it has all the accuracy and much of the minuteness of a guide book, without any of its dullness. The addition of a map, on a large scale, prepared especially for the work, adds greatly to the value of the book, and make it indispensable to all who visit that region. Those who do not go to the Maine forests—that large class of stay-at-home travellers—will find this work the next best thing to a tour, as it presents the peculiar features of the country, the incidents of travel and camp life, in a fresh and pleasing style, while the descriptions are supplemented by a profusion of engravings largely the result of having a "Camera" with the "Canoe," though they are by no means all from photographs. Sketches by the author himself, and several artist-friends, give a pleasing variety, in which the humorous and sometimes ludicrous aspects of canoeing and camping are not overlooked. The general excellence of the engravings deserves mention, and some of them might be taken as examples of the present perfection to which the engraver's art has reached in this country. The paper, press work, and binding, all combine to give the work a fitting setting, and make it one of the most beautiful volumes yet added to the tourist's library. Price, \$1.50.

**The American Bicyclist.**—This work, which was noticed a few months ago, now comes to us enlarged by an "Appendix for 1880," which adds 60 pages of new matter of interest to all who run on wheels.

**Sending Fruit.**—Some send us specimens that we may see how fine they are, and others send them to be named. Some think to pay the express charges, others do not. If it were only now and then we were required to pay express charges, it would be of little consequence, but when this occurs several times a day, it amounts to a larger tax than we care to pay. Our friends should bear this in mind when sending fruit.

**Special Cultures—Tobacco and Onions.**—Within a few days we have had letters asking about the cultivation of Tobacco and Onions, to answer which in full would require us to write several treatises. It was to meet just such inquiries as these that we several years ago offered prizes for the best essays on their cultivation. Several essays besides those taking the prizes are printed, and each little book contains fuller information on the crops than can be found elsewhere. The same may be said of Hops and Flax.

**Wild Hops.**—"Mrs. E. J. V., Howard Co., Neb., sends a specimen of Hops found growing in the State, asks if it is of a good kind for cultivation, and how to grow them from seed. The chief difference in the few varieties of hops is in the size of the clusters, and those sent are of very good size, the largest we have seen from wild vines. Hops are not multiplied from seed. It is a plant with separated flowers, some bearing all staminate or sterile flowers, and others all pistillate or fertile ones. When seeds are sown, a large share of the plants may be sterile, and this can not be ascertained until the second year at least. They are propagated by sets, or shoots taken from the old plants in early spring. Shoots 4 to 6 inches long are used. In cultivated plants, each hill, or old root, pushes a great many more shoots than are needed, and the excess are taken for new plantations.

**The "American Wonder" Pea.**—Last year we had a very short row of this variety in a favorable season; this year we had a row over 200 feet long, in a most unfavorable season. Taking the two together we have formed a most favorable opinion of the "American Wonder" which is based upon these facts—1st, It

is dwarf; 2d, it is early; 3d, it is productive; 4th, it is of most excellent quality. While our experience does not allow us to make a positive assertion, we have no doubt that it will be found to yield more from the same area than any other early pea, because it can be planted so much closer than the sorts that require hush. It grows only about a foot high, and each plant is well loaded with, in favorable seasons, long, well filled pods. With us these have matured all together, allowing the crop to be taken at one picking, an excellent feature in a market pea, and while not considered so desirable in the family garden, it will not be found an objection when provided against by successive sowings. For quality on the table it is easily first class. Messrs. B. K. Bliss & Sons deserve the congratulations of the whole gardening community for having introduced so excellent a variety of this popular vegetable.

**Shirts by Mail.**—The Newark Shirt Company, Newark, N. J., at one time advertised to send shirts by mail. Though they have not advertised for a long time orders continue to come to them, and we would relieve them of the trouble of returning them by saying that they have discontinued their retail and mailing departments, and confine themselves to manufacturing for the trade.

**Keep the Head Cool.**—There is reason in the notion that a cabbage-leaf worn on the head, within the hat, will prevent sun-stroke. There is no special virtue in cabbage-leaves, any other leaves will answer—so will wet paper. Any thing of the kind worn upon the head will serve to protect it from the hot sun.

**Strawberry Jam.**—A correspondent wishing us to name a variety of strawberry, placed the fruit in a box, with alternate layers of cotton-hatting, the box being but partly full. When they reached us, there was too much cotton among the strawberries, and too much strawberry among the cotton, for either to be especially useful. Strawberries need no packing material, beyond what their hulls, which should always be left on, afford, and the box should be so full, that they can not shake.

**The White Grub and June Bug.**—Last month, p. 247, we mentioned the success of W. C. Stiles, Jr., of W. Va. in catching June Bugs, by the use of a lantern set in a pan of water upon which was a layer of coal oil. Mr. S. writes that he finds the trap to answer as well without the oil as with, and that no beetles appear until two hours after sunset, hence the expense of keeping up the lights before that time may be saved. He says that he has caught with two traps in seven nights over 1,500 June Bugs! This is a very important matter. If this meant only the destruction of the same number of white grubs, it would be worth all the trouble; but allowing the beetles to be half males, which is hardly probable, and the female to lay the small number of 100 eggs, this would make 75,000 white grubs which are—not killed off, but prevented from existing at all.

**Hats for Horses.**—In the hot days of summer, one rarely meets a dray horse or other hard-worked horse, without some contrivance for preventing the direct rays of the sun from beating directly upon its head. Some styles of these hats were given last Aug., on page 314, and there are a vast number of other methods by which the same end—the comfort of the horse—and it may be its safety, for horses have been known to be overcome by heat, and suffer greatly on its account.

**The Army Worm and Grape Vines.**—Just as these pages are being closed, the report comes that in the vine-growing portions of Burlington and Ocean Cos., N. J., the Army Worm is devastating the vineyards. The vine has not before been considered liable to the attacks of this voracious eater, which seems to develop new likings in its present visit.

**"Rural Improvement,"** by B. G. Northrop, Sec'y of the Conn. State Board of Education, is the title of a pamphlet of about 50 pages, sent us by the author. In February, 1878, we gave an account of the good work done by the "Village Improvement Association" at Litchfield, Conn. In various other villages and towns in Conn. are other Associations actively engaged in improving the surroundings of the homes of its members, and consequently increasing the beauty and attractiveness of the whole town. The existence of these Societies, and the results they have produced, are largely due to the efforts of Mr. Northrop. His official duties taking him to all parts of the State, he has been able to see where such improvements were needed; having a happy way of presenting the subject, and a talent for organizing, he had only to call the people together, point out what should be done, and an "Improvement Association" was formed forthwith. The present treatise is a plea for such Associations, pointing out the good work they can do, not only in increasing the attractiveness of a place, but its healthfulness. It also presents the economic value of tree-

planting, and gives useful hints to Railroad Corporations and manufacturers as to embellishing the grounds around their stations and factories. A form of Constitution for a Village Improvement Association is given. The work is quite as much needed elsewhere as in Connecticut; indeed, there is not a village in the land but might be increased in beauty, and consequently in value, by following the hints here given. Sent post-paid for 25 cents.

**Beet Root Sugar, and Cultivation of the Beet,** by E. B. Grant. Boston: Lee & Shephard. This work bears upon its title page 1880—and there is nothing in its preface to show that it is not a new work. One need not read far to learn that he has in hand an old work, which, however valuable in itself, is far behind the present condition of the beet-sugar interest. The book originally appeared in 1866, and does not seem to be modified in any respect in this reprint. The work contains much that is useful, and has long formed a part of the standard literature of the subject. Price, \$1.25.

**The Mississippi Valley Hort. Society.**—Our usual Fair List will show that this Society's exhibition will be held at St. Louis, Mo., Sept. 7th, 8th and 9th—but something more than this brief announcement is required in this case, as it is the first exhibition of an Association that is apparently to become one of the most important among our many Horticultural Societies. Delegates from the horticultural societies of the different States forming the Mississippi Valley, from that of Texas on the south to that of Iowa on the north, met some time last spring and effected a preliminary organization and appointed an Executive Committee to arrange for a meeting and exhibition in September. Parker Earle, President Ill. Hort. Soc. is Chairman of this Committee, and S. M. Tracy, Sec. Mo. Hort. Soc., is Secretary; his address is 600 Olive street, St. Louis. Covering so many degrees of latitude by its territory, the coming exhibition should be a most varied and interesting one. It is to be held at the hall of the St. Louis Merchants Exchange, which is said to be "the largest and finest in America." The Exchange moreover guarantees the sum of \$2,500, which allows of liberal premiums, a schedule of which is before us. For the best collections of each of the different fruits \$100 is offered for apples and \$50 each for pears, peaches, and grapes. With a Society like this, it becomes a question whether it is desirable to offer money premiums at all. While it may be well to do this at its first exhibition, we think it will be wise to have medals and certificates instead of money—as this will relieve the Society from an element of weakness that always attaches to those societies, the treasuries of which depend upon the annual dues of members. While this Society is intended especially to promote the interests of the horticulturists of the Mississippi Valley, the co-operation is invited of "all interested in the horticultural growth of the country, without regard to locality." We give this new Association our best wishes for its success, and hope that many a one outside of the "Valley" may find it convenient to be present next September.

**Practical Camellia Culture,** by Robert J. Halliday, Baltimore, Md. Mr. Halliday has long been known as a Camellia grower of large experience, and the results of that experience are here embodied in a work of about 140 pages. It is one of those satisfactory horticultural works, that seem to be peculiar to this country. It tells all that there is to be told, in a plain, straight forward way, beginning at the beginning, and treating every part in full. It is a matter of regret that in so useful a work, the engravings are not in keeping with the text—still they are intelligible, and that is the main point in a practical work.

**Practical Artificial Incubation,** by J. F. Ferris, Editor of Poultry Monthly, Albany, the Ferris Publishing Company. But few are aware of the widespread interest in artificial incubation that his correspondence makes known to an editor. The matter appears to have attained to too great success, to be disregarded, and it is not yet sufficiently successful to be generally adopted. Whoever will make the last step, and give us an incubator that will produce chicks with as much certainty as the old hen, will be a public benefactor. In this work, Mr. Ferris shows what has been done in the artificial hatching and caring for chicks, and presents various incubators with the claims made for them, by their inventors. This work allows those who are investigating the subject, to have the materials together in a compact form for ready comparison. Price, post-paid, 50 cents.

**Potato Bug Enemy.**—"W. A., Lebanon, N. Y., sends Potato Beetles, covered with a minute parasitic insect. It is by no means new, and we wish it were more common. You are right in supposing it to be an enemy to the Beetle. It is a mite, first described by Prof. Riley as *Tropoda Americana*, and figured by him in his work on "Potato Pests." The same was reproduced in the *American Agriculturist* for July 1878, page 267.

**Never Keep an Old Sheep.**—"It is a piece of folly to keep old sheep;" says a great sheep grower, and that with good reason. The end of every sheep is the shambles; it may give one or more fleeces of wool on the way, but not so many that the carcass will cost more to fatten than it will bring. A ewe should not bear lambs more than five times; at the end of this period the carcass will, with proper care, be round and full, and can be fattened with comparative ease. Should the animal be a pure blood and of a family or strain of blood that is scarce, the case will be otherwise, for the carcass is then considered of very little value as compared with that of the offspring that may be obtained.

**Value of a "Calf Feeder."**—It is settled beyond a doubt that allowing a calf to suck is an injury to the cow, while at the same time it is the best method of feeding the calf. But as the cow is above the calf in value and importance, it is economy to remove the offspring and that so soon as the milk is fit to use—after the third day. The objection to the system of allowing calves to drink from a pail, namely: that no saliva of any account is mingled with the fast swallowed milk is overcome by the "Calf-Feeder," which is now used to some extent and highly prized by those who know its value. The "Feeder" is a covered pail arranged with a rubber teat on the cover and connected with a tube, the open end of which is in the bottom of the pail. The calf is soon taught to use the feeder and by the process of suction—quite natural to the calf—the saliva flows rapidly and is mixed with the milk; and the calf is better satisfied as is also the owner when the young animal is turned over to the butcher or is kept for a longer period.

**Wooden Shoes.**—The newly arrived German immigrant often appears in the shoes to which he was accustomed at home. These are large *sabots*, or wooden dug-outs, and are clumsy in appearance as well as noisy upon the floor or pavement. They have one thing to commend them, each one can make his own without the aid of the shoemaker. However unsightly they may be, these shoes are really serviceable; wood being a poor conductor, they keep the feet warm, and being impervious to water, keep them dry. Indeed there is so much in favor of the use of wood for the soles, at least, of shoes, that several American manufacturers have adopted it for certain styles. A firm in Pennsylvania several years ago made wood-soled shoes, and we for some years kept a pair of these to slip on when going into the garden or field in damp, cold weather, and found them very useful. There are many whose occupations require shoes that shall be both durable and comfortable; this is especially the case with farmers, who are exposed to all sorts of weather, and we are glad to learn from our advertising columns that shoes with wooden soles are still made by Chas. W. Copeland, of Boston, and more than that, are well made. Were they to come into general use among farmers, we do not doubt that many a fit of illness would be prevented by those who would wear them.

**Sorghum Machinery.**—Sometimes a catalogue is more than a mere list of articles and their prices, and gives besides matters of interest relating to the uses of the materials offered. The catalogue of the Blymyer Manufacturing Company is of this kind, and besides offering Sorghum machinery, it tells a good deal about Sorghum. This firm were among the first to meet the wants of farmers by providing them with Sorghum machinery at the time when this crop was first introduced, and they have since kept pace with all the improvements in this important branch of agriculture. It is a matter of regret that in an article on Sorghum in March last, all reference to this firm was inadvertently omitted—and it is only an act of justice to say, that whatever position sorghum culture may occupy in the future, will be largely due to the labors of this Company in the past. Their catalogue shows that they are prepared to meet all the new demands created by the improved variety of Sorghum with the machinery for working it up into the best products and that in the quickest and best manner.

**The Potato Disease in Europe.**—The heavy losses which the farmers of Great Britain have experienced during the last five years from the Potato Rot, have given rise to serious doubts whether this valuable crop can be grown with profit in those countries in the future. Like every other agricultural trouble, this one stimulates thought, and leads to new methods of culture, that are experimental, and it may be beneficial. Of late much attention has been directed towards the finding of a "disease-proof" variety of potato, or at least the production of sorts, that though attacked by the Rot, are able to withstand it, and not be seriously injured. To encourage this work of finding out the best kind of potato, prizes have been offered at different times, and elaborate experiments, to test the varieties, have been carried out, without any very satisfactory results. But a great deal of good has grown out of this seeking for a disease-proof potato, especially in the way of improving

the varieties through carefully selecting the tubers, and their proper cultivation. Knowing that the disease is a parasitic fungus (*Peronospora infestans*), the development of which is favored by warm, moist weather, and hindered by the opposite, there is little hope of finding a variety of potato that will differ so materially from all others, that it will be proof against the attacks of this fungus. There are, nevertheless, certain precautionary measures to be taken. These are embodied in brief, in an English review of Mr. Bravender's treatise, "The Potato Disease, and How To Prevent It," from which we take the following: "Secure good seed if you can, entirely free from disease. Plant early—on light land, 5 inches; on heavy land, 3 inches deep—and earth up well. Have the rows from 2 feet 8 inches to 3 feet apart in gardens, and 3 feet or more in the field for late varieties; may be rather less for others. If there is danger of frost, cover along the rows with short litter, about enough to hide the plants from view. Plant, if possible, in land not occupied by the same crop the previous year; and plant the late kinds, if possible, in a field by themselves. Use medium size sets, or cut sets if large, about 12 to 18 inches apart in the row, according to size. If the sets are very small, they need not be so far apart. Manure in autumn, and use potash salts or bone phosphate in the spring; or else make a compost of manure and earth, ashes, etc. Earth up twice. The tops may be cut off those required for seed, if the tubers are large enough. Harvest late kinds sooner than is usually done. If there appears any disease amongst the crop, sorting over will be required. If you have the convenience, store your crop for a time, and not put in pits until November. On harvesting, separate the diseased from the healthy ones." We have more or less of the Potato Rot in this country, sometimes to the destruction, whole or partial, of the crop, and the above rules may properly be observed by American farmers. The direction given to "earth up twice," is not needed with us, while in the moist climate of Britain, the crop is benefited by "hilling," the conditions are quite different with us, and unless in a very wet summer, flat culture gives better returns. While the potato crop is an important one with us, its failure does not bring such consequences to our farmers, as it does to the Irish peasant, whose life, and that of his family, may be said to almost depend upon the success of their all important potato crop.

**Breeding Thorough-bred Stock.**—As we were a short time ago looking over a fine herd of thorough-bred stock, upon a farm which we visited, while we did not covet it, we thought that no one, as he looked over these finely proportioned animals, could refrain from wishing to have a similar herd for himself. There is a charm in the whole matter of stock-breeding, and especially so if one has fine animals at the start, and their best points are made more fixed and prominent as the generations pass. But while looking at these animals and listening to the explanation of this and that point of excellence, the thought naturally suggested itself: is not this breeding of pure-bloods with the care and nicety, here manifest, a sort of fancy farming that only a few can hope to indulge in? What capital is invested! A thousand or fifteen hundred dollars, which in the breeder's view is not much, for a cow, is far beyond the ability of the average farmer. In order to succeed as a good breeder of thorough-bred stock, the first requisite seems to be a good bank account, and the second a clear idea of what one is breeding for—an end towards which all his skill—for he must be skillful—must tend. The proportion of men having the requisites for breeders of thoroughbred stock is small; and any one who contemplates the task should at the outset be sure that he possesses them. We would not discourage any one from undertaking the rearing of a herd of pure-blooded animals; but simply caution against going into it without a thorough preparation for the task. It is only when entered into intelligently and with the requisite capital that it is made to pay—and even then it can be remunerative only after some years of constant outgo with no corresponding income. The breeding of pure-bred animals is one of the most important departments of agriculture, for upon the existence and growth of such herds does the improvement of farm stock in general largely depend. If all our pure blood animals were taken from us, or rather, if they were scattered broadcast over the country, the work of centuries would be undone, but so long as these animals are kept in herds, with a judicious outflow of the pure blood to be mingled with the common stock of the country, they contribute largely to the general good by gradually advancing the average grade of our farm animals. It is well that there are men of sufficient means, combined with a love for improved live stock, who will keep herds of thoroughbreds, for they can be kept pure only with great care and often at great expense. Whatever may be their motives in building up fine herds, such persons can not well avoid being public benefactors, and we are glad to believe that there are some sufficiently public-spirited who do it mainly because it will conduce to the general good.

An Indian said to a young man who chaffed him upon his bald head: "Young man, when my head gets as soft as yours I can raise hair to sell."  
It is a great piece of folly for a man to be always ready to meet trouble half way. If he would put all the journey on trouble, he might never meet it at all.  
Patrick having been told that Dr. Peters had found an asteroid, remarked: "Bedad, he may have his asteroid, but as for meself I prefer a horse ter ride."  
"Will you name the bones of the head?" said a teacher to one of his class. "I've got 'em all in my head, teacher," replied the pupil, "but I can't give 'em."  
A Minnesota farmer who has five grown up daughters, has sued the county on a claim that his residence has been used as a "Court-house" for the past two years.  
"If Jones undertakes to pull my ears," said a loud-mouthed fellow on a street corner, "he will just have his hands full." The crowd looked at the man's ears and laughed.  
This is the way the married editor sums up Lent: "The hen which lays the Easter egg is a great bird, but it takes the goose which lays the golden egg to bring Easter bonnets."  
If Noah had foreseen the future, and killed the two mosquitoes which took refuge in the ark, he would have rendered some of the strongest words in the English language unnecessary.  
A little girl read a composition before the minister. The subject was, "A Cow." She weaved in this complimentary sentence: "The cow is the most useful animal in the world except religion."  
"That is what I call a finished sermon," said a lady to her husband, as they wended their way from church.—"Yes," was the reply with a yawn, "but, do you know, I thought it never would be."  
Newly married husband: "This is a friend of mine, my dear—a friend of twenty years' standing." His bride: "Good gracious. Then pray give him a seat, for I am sure he must be tired."  
Dr. Charles Smart of the army is looking scientifically into the well and eastern water of New Orleans, to ascertain what the people of that city drink. We fear the doctor is on the wrong scent.  
The Cleveland "Herald" advises Christians to hire a steamboat, give a Sunday excursion, and then suddenly open religious services on the crowd of loafers. They must either listen or jump overboard.  
"Do you use many flowers on your table?" asked Mrs. Murray Hill of a southern visitor.—"Well, yes," was the reply; "we have wheat and rye bread for breakfast, but the old man will stick to corn dodgers."  
A school boy being asked by his teacher how he should

flog him, replied, "If you please, sir, I should like to have it on the Italian system of penmanship, the heavy strokes upward, and the downward ones light."

Kankakee has a justice who beats them all in the way of doing up a job of matrimonial splicing with neatness and despatch. "This is his formula: 'Have 'er?'—'Yes.'—'Have 'im?'—'Yes.'—'Married?'—'Yes.'"

"What a beautiful sight!" exclaimed Mrs. Jones rapturously, as she looked out over the beautiful scenery from a Pennsylvania railroad car. "Yes," replied Jones, without raising his eyes from his paper, "anthracite."

A married man bought a spring chicken in the market the other morning, and now he thinks the reason it was called spring chicken is because it will take him till next spring to carve it, unless he uses nitro-glycerine.

"Man," says Victor Hugo, "was the conundrum of the eighteenth century; woman is the conundrum of the nineteenth century." An American editor adds: "We can't guess her, but will never give her up—no, never!"

"What's in a name?" Ah, William, you didn't know everything, that's certain. Salt can be bought for a few cents a quart, but call it Chloride of Sodium, and the apothecary will charge you half a dollar for one scruple.

The sporting season has arrived, when the amateur hunter goes into the forest and shoots the farmer's \$10 cow, under the impression that it is a deer, and afterward pays the farmer \$25 to settle the matter and keep it quiet.

The enemies of the Czar of Russia will attempt shooting him, blowing him up and stabbing him, and still he will live until some day when he is fooling with a revolver that isn't loaded, he'll get the whole top of his head blown off.

A senior, after vainly trying to explain some scientific theory to his fair innamorata, said: "The question is difficult, and I don't see what I can do to make it clearer?"—"Suppose you pop it?" whispered the blushing damsel.

Lives of grocerymen remind us  
They can make their starch half lime,  
And with sugar wholly blind us,  
Putting sand in all the time.

"Why, you'd better knock the door down. What do you want?"—"Och, my darling! don't let me wake any of your family. I'm just using you knocker to wake the people next door. I'm locked out, dye see, and they've niver a knocker."

Little Rhode Island is sensible enough to pass a law against pigeon shooting.—[*New Orleans Picayune*.] H'm, yes. The shot used to scatter into other States so badly that Connecticut and Massachusetts chickens were in danger.—[*New Haven Register*.]

A lecturer was explaining to a little girl how a lobster cast his shell when he had outgrown it. Said he, "What do you do when you have outgrown your clothes? You cast them aside, do you not?"—"Oh, no," replied the little one, "we let out the tucks."

A native of the Green Isle was pressed by the collector of a water company for payment of the water rate; to which modest request he returned the following answer: "Sure I pay tin shillings a year for wather, and many's the day it's off for a whole wake!"

"Is this my train?" asked a traveller at the Kansas Pacific depot, of a lounge.—"I don't know, but I guess not," was the doubtful reply. "I see its got the name of the railroad company on the side, and I expect it belongs to them. Have you lost a train anywhere?"

Mother (at tea-table): "Jack, who helped you to those three tarts?"—Jack (age seven): "The Lord."—Mother: "The Lord? Why, what do you mean, Jack?"—Jack: "Well, I helped mother said yesterday that the Lord helps those who help themselves."

He was a very stubborn little five-year-old boy. The boy's mother determined to conquer him, and, having administered a severe chastisement, she said: "Will you mind now, Johnny?"—With sobs and cries he replied: "Yes, mamma, I will, but I hate to, awfully."

We frequently hear a lady exclaim, "Oh, dear! I wish I were a man!" but we do not remember ever hearing a man wish himself a woman. No; man never dared allow his wishes so soar so high. He is content to admire rather than be the thing admired. N. B.—This is not taffy.

A little girl passing the Washington Statue, lately, asked a lady who was with her if Washington was buried there. "No," said the lady.—"Where is he buried?" said the little girl.—"I don't know," said the lady.—"Then I guess you don't read your Bible much," said little innocence.

A Tennessee man accidentally shot a dog, and in trying to explain to the owner how it occurred accidentally shot him. A coroner thought he ought to explain how he shot the man, but couldn't get a jury that was willing to listen to the explanation; they were kind of shy of him, as it were.

"Have you any objects of interest in the vicinity?" the tourist asked the Burlington man.—"I have, I have," eagerly replied the other, "but I can't get at it to show it to you. It's a ninety days' note and its down in the bank now, drawing interest like a horse race or a mustard plaster."

"Papa," said he, as he was shown some pictures in a book Santa Claus had left him, "Papa, why does camels have such big hunches on their backs?" The information received not being very satisfactory, he at length solved the difficulty himself. "Why, I know, papa," said he, "it's so's they'll be camels."

Grammar!—Invalid: I've had a wretched night, Mrs. Wobbles.—Nurse: Dear me, sir, I thought you slept most comfortable.—Invalid (with a groan): Oh, Mrs. Wobbles, do use the adverb.—Nurse: Yes, sir, I'll see about it directly, sir, but—(puzzled)—I recly don't think there's one in the 'ouse, sir!

A little boy being asked by another boy what he was doing now, replied, "I am cashier in a clothing store."—"You, cashier!" said the other in amazement.—"Yes," said the little chap, "that's what the clerks call me. A hundred times a day they hoiler 'cashier.'" "Cash! here!" was what the clerks said.

Tradesman to country customer who has come to complain of the quality of his matches: "Not light? Why, I have only to draw them smartly across my cord breeches, and they blaze instantly."—Customer: "Yes, but what's that to me? I can't come a matter of four mile for your old breeches every time we wants a light."

Pat: "Well, Dan, and have ye heard the news—have ye heard that Rory the miller's dead?"—Dan: "Rory the miller is it that's dead now? but ye don't say so, and he was a young man too."—Pat: "Faith, an' that's thrue for ye, Dan; he was such a young man, now, that I expected to see him at my own funeral instead of me going to his."

"Where is your mother!" said a worthy man to a little street miser. She answered diffidently. "She is dead."—"Have you no father?"—"Yes, sir; but he is sick."—"What ails him?" continued the questioner.—"He has got a sore finger, sir."—"Indeed?"—"Yes, sir."—"Why don't he cut it off, then?"—"Please, sir, he hain't got any money to buy a knife."

An original thinker never thinks the things that other people think.—[*New Orleans Picayune*.] But when one thinks that another is thinking things that no other could think, and he thinks he will try to outdo him by thinking greater things than he thinks the other is thinking, we think he is about as foolish as we are in thinking of this thing at all.—Boston *Advertiser*.

No. 131—Price 65 cts.

# THE FERGUSON BUREAU CREAMERY.

Surpasses all others in quantity and quality of butter made. It secures matured and ripened cream, which makes butter of the best texture, flavor, and of unequalled keeping quality. It excludes flies, dust and odors; is constantly at the correct temperature (38° to 60°); has room for the cream and butter, and saves three-fourths the labor. It can be used with either ice or water, and both summer and winter.

**THE FERGUSON CONFESSION CHURN** is the best. It combines scientific principles with the best labor saving devices, each floor or paddles. Brings the butter in granular form, and secures the largest yield. Before buying any other Churn or Creamer; or any pans, or cans, send for large illustrated circular to **THE FERGUSON MFG CO., Burlington, Vt.** Reliable Agents Wanted.

## BUTTER WORKER.

Lilly's Patent.

Won First Premium at the American Institute Fair, New York, in 1878; at the Fair of the Penn. State Agricultural Society in 1879; at the Dairyman's Fair at Delbi. N. Y., in 1879, and at County Fairs innumerable. Acknowledged to be the **only self-feeding and reliable machine in the market.** Descriptive circular sent free.

C. H. R. TRIEBELS, 316 Race St., Phila., Pa.

## HOUSE-KEEPERS, ATTENTION!

THE GLOBE WASHBOARD AND THE IMPROVED UNION CHURN

Are the best in the world. Neither have any equals. Over 600,000 **Globe Washboards** sold in 1879. No more sore hands or torn clothes on inferior washboards. Buy it and try it. The Improved Union Churn is the perfect butter-maker. Easier and quicker than by any others. One trial will convince any one of the fact. Send for circulars with full details. Liberal terms to dealers.

UNION MANFG CO., Toledo, Ohio.

## Rectangular and Square BOX CHURNS

**Cheapest and Best.** No inside fixtures, and always reliable. Six sizes of each kind and name. Three sizes of the **Lever Butter Worker** made. Best material used, and every Churn and Butter Worker warranted exactly as represented. One Churn at wholesale where we have no agent. Send Postal for Circulars. AGENTS WANTED.

CORNISH & CURTIS, Fort Atkinson, Wis.

## BUTTER WORKER.

The most effective, simple and convenient yet invented. Works 30 lbs. in less than 5 minutes. Thoroughly working out buttermilk and mixing in the salt. **AGENTS WANTED.** Send for Circular.

A. H. REID, 6 N. Eighteenth St., Philadelphia, Pa.

## POULTRY WORLD.

A monthly magazine, the oldest, largest, and best periodical devoted entirely to poultry ever published. Splendidly illustrated. \$1.25 per year. Also the **American Poultry Yard**, the only weekly paper devoted entirely to poultry in existence. \$1.50 per year. Both papers for \$2.00. A sample copy of both mailed on receipt of nine cents in postage stamps.

Address H. H. STODDARD, Hartford, Ct.

## JERSEY RED

Hogs still ahead in heavy weights. Fine stock of spring pigs at low prices. Address J. S. COLLINS, Moorestown, N. J.

A perfect Double Tree.  
A perfect Equalizer.  
A perfect Stretcher.

Can be applied to any implement, either with or without tongue.

M. E. BUNGER & CO.,

Indianapolis, Ind.

MAKERS.

Light, Strong and Simple.

## PIGS.

This spring's **Chester White, Berkshire, Yorkshire, Jersey Red, Poland-China, and Essex Pigs** was never finer, at the same time our prices are unusually low. Also extra **Cornish and Southdown Lambs.** Do not fail to write us before purchasing. Illustrated Catalogue mailed on application.

BENSON, MAULE & CO., 223 Church St., Philadelphia, Penn.

## I. X. L. SPRING TUG LINK.

Patented Feb. 30, 1880

Affords the greatest protection to **HORSES**, Harness, Wagons, Plows, Mowers and Reapers. Reliable and guaranteed as represented. Protect your Horse, save your money, by procuring the celebrated **D. RISHER & CO'S I. X. L. Spring Tug Link.** Ask your hardware man for them, or send to **D. RISHER & CO.,** Corner of 4th and Wood Streets, Pittsburgh, Pa.

## HARNESS.

A GOOD, SUBSTANTIAL HARNESS, Hand-made, full nickel-plated, for \$13.50. Call and see or send for sample. Also a complete assortment of **RIDING SADDLES, BRIDLES, CARRIAGE ROBES, and DUSTERS, HORSE CLOTHING, and NETS.**

C. B. SMITH & CO., 40 Warren St., New York.

## ATTENTION, OWNERS OF HORSES.

**THE ZINC COLLAR PAD** Is the only permanent, reliable, and sensible pad for sore necked horses or mules ever made, being smooth metal always in order, it does not wear the mane. Over 1,500,000 in use. Pads of other material soon become worthless, and have no curative properties whatever. Zinc Pads are sold by all Saddlery Houses and Harness Makers. Ask for them. Manufactured by **ZINC COLLAR PAD CO.,** Buchanan, Mich.

## NOVELTY INCUBATOR.

I offer this as the simplest, cheapest, most easily run, and best incubator. Daily cost of running, 3 cts. for fuel and a few minutes attention. Hatches 50 to 90 per cent almost surely. Holds 100 Eggs. Price, \$25.00.

Also **NOVELTY HYDRO-MOTHER**, Price \$8.

A. C. ATKINS, Orange, N. J.

## MONEY IN POULTRY.

45 Medals and diplomas have been awarded to Prof. A. Corbett, No 7 Warren St., N. Y., for his new process for hatching and raising poultry in horse manure. For catalogue, send 3-cent P. O. stamp.

**RIVERSIDE FARM.**—Jerseys, Berkshires, and Cotswolds imported, bred, and for sale. Bronze Turkeys, Pekin Ducks, and Light Brahmas. Send stamp for catalogue. C. P. MATTOCKS, Portland, Me.

## THOROUGHbred AND CROSS-BREED

OR GRADE JERSEY STOCK.

5 fresh cows, 4 to 8 years old, with or without calves.  
5 thoroughbred Jersey Bulls, 1 to 5 years old.

5 Heifers, 8 to 11 months old.

All the above are, or can be registered in the A. J. C. Club Register. 25 cross-breed heifers and cows, 2 to 7 years old. These are a mixture of the two breeds, Jerseys and Ayrshires; several are now fresh, and the balance within the next two months. The best family cows ever bred, all rich milkers and butter-makers; some of them 2 lb. cows, beautiful in form and color. Orders solicited for calves of either breed, deliverable when weaned and ready to ship at 2 to 3 months old. My prices range from \$45 for a high grade beef calf, to \$400 for my best thoroughbred cow and calf. April, 1880. THOMAS FITCH, New London, Conn.

TO ALL WHOM IT MAY CONCERN.—My letter to J. R. McFarland under date of Nov. 15th, 1879, and embodied in the Champion Mowing Machine Co.'s advt, which appears on the last cover page of the March No. of the *American Agriculturist* for 1880, is so connected with the other matter as to cause many to believe that I endorse the claim made by the Champion Co. in the Oct. Supplement of the *Am. Agriculturist* to the "Highest Prize for Best Work and Lightness of Draft over all other competitors" at the Field Trial of Mowing Machines by the Queens Co. Ag'l Society, at Mineola, N. Y., June, 1879. That none may be deceived as to my position in the matter, I hereby certify that the "Eureka" received the first prize, the "Eureka" the second prize, and the Champion (rear) the third prize. J. HOWARD RUSHMORE, Sect'y Queens Co. Ag'l Society.

**THE GREAT AMERICAN TEA COMPANY**

Try our NEW CROP TEAS, all kinds, 60c. per lb. This is the first time these Teas have ever been offered at 60c. Same quality sells in stores for 80c. and \$1.00 per lb.

31 & 33 Vesey St. NEW YORK.

P. O. Box 4235

Sets of numbers sent to the office will be bound in our regular style for 75 cents (80 cents extra if to be returned by mail). Missing numbers in such volumes supplied at 10 cents each.—Any Numbers of the paper issued for 23 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.50. Clubs of Subscribers can be increased at any time, at the club rates, if new members begin at same date as the original club.

## AMERICAN Grape Growing AND WINE MAKING.

AND

## WINE MAKING.

BY

GEORGE HUSMANN.

PROFESSOR OF HORTICULTURE IN THE UNIVERSITY OF MISSOURI.

With Contributions from Well-known Grape Growers, giving

A WIDE RANGE OF EXPERIENCE.

ILLUSTRATED.

The work is a complete guide for novices in the culture of the Vine, and at the same time may be regarded as a summing up of everything of importance and value bearing upon this industry. Special attention is devoted to the Phylloxera, whose destruction of the roots of vines had very much to do in bringing on the collapse of grape growing, and the destruction of the vineyards of France. The experiments and discoveries of Husmann and his associates in connection with this destructive little insect, are, for the first time, presented in this volume, and will prove of incalculable benefit to the grape growing interests of this and other lands.

The book is copiously illustrated with sketches from the author, which add materially to its value.

PRICE, POST-PAID, \$1.50.

ORANGE JUDD COMPANY,

245 BROADWAY, NEW YORK.

## BAT AND TRAP.

As here represented, the articles necessary to play this game are one bat, one ball, and the trap. Any number of persons can engage in the game, from one to five on a side, and it can be played by ladies and gentlemen, or girls and boys. It can be played on the lawn, meadow, or any place where baseball, lawn tennis, or croquet

are played. The ground need not be smooth as for croquet. It is very fascinating, and has as much variety as any other popular game. Rules accompany each game, and they are easily learned.

Price, \$2.00.

Expressage to be paid by the Recipient.

ORANGE JUDD CO., 245 Broadway, New York.

NEW YORK, AUGUST, 1880.

NEW SERIES—No. 403.

A FARMER'S HOLIDAY AT THE TROUT STREAM.

What have farmers to do with a sporting scene, and sport? some Gradgrind may ask. In our view much! Work, hard work, and plenty of it, is the lot of every successful farmer. But the farmer's life should not be all work; he of all men

deserves, for he fairly earns, his term of recreation, and he should have it too. Many find their highest enjoyment in angling. If it is proper for any one, the sport is proper for the farmer, if his tastes so incline, when he leaves his toil for a

change of scene. A day by a wild mountain stream, in the dark, still pools, where the trout await his coming, will furnish immediate pleasure, but its greatest value will be in the after-memories that will go far to make present labor lighter.

## AMERICAN AGRICULTURIST.

NEW YORK, AUGUST, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

It is to be remembered that the *American Agriculturist* circulates over a vast territory, and it follows, from the great difference in the seasons, etc., that these hints must be of a general character. Good judgment must, therefore, be used in applying them to any particular section or locality. It is evident that no one rule as to planting, sowing, harvesting, etc., can apply everywhere.

**Sowing Wheat.**—When wheat follows oats, the oat stubble should be plowed as soon as the crop is removed from the field, otherwise the dry weather, that so frequently comes in early autumn, will make the soil dry and hard, and it then can only be worked with difficulty. Wheat requires a fine, mellow soil, and if any clods remain after the first harrowing, the work of pulverizing the soil should be continued until all clods are reduced to a fine state. The roller and the Disk harrow are both excellent implements in bringing the soil into a proper condition.

**Drilling** is by far the best method of sowing; it secures uniformity in depth, and saves seed by putting all the grains in a proper place for growth. Five or six pecks of grain is sufficient seed per acre when the drill is used. Of late some farmers are testing the value of cultivating wheat, and their results are almost uniformly in favor of the practice. In sowing, the alternate spouts of the grain drill are closed, and the seed sown in rows about 16 inches apart. It is not difficult to construct a cultivator that will work between these rows by means of which the soil may be kept loose and free from weeds. We wish to receive full reports from those who have been cultivating their wheat the past year.

**Seed.**—Much depends upon the variety of wheat sown. Of the several kinds now “in the field,” the Clawson takes very high rank, and is the one found to be generally preferred in the wheat regions we have recently visited.

**Early Sowing** is best except when there is danger from the Hessian fly, when the late sowing is preferred, but owing to the poor growth made in autumn only an average crop may be expected from sowing

late to escape the fly—it is a choice between two evils, the lesser of which is sowing the seed late.

**Rye** is not so valuable a crop as wheat; but it has the advantage over wheat of doing well on a poorer soil. It should be borne in mind that a soil that is rich enough to grow a good crop of rye can, by a dressing of 250 to 300 pounds of fertilizer, be made to produce a much more profitable crop of wheat. If the rye is grown for the straw, in special cases, the rye crop may be more valuable than wheat; but as a grain crop the wheat takes the front rank.

**Fall Fodder.**—White turnips may be sown this month. With the use of manure or artificial fertilizers, an oat stubble may be made to produce a crop of 600 to 800 bushels per acre. These roots make excellent feed for all kinds of stock, and will keep in good condition until January.

**For Fall Pasture**, rye, or millet, may be sown early this month, on rich and thoroughly prepared soil. If wintered this fall, the rye will make a good crop for the spring soiling of the farm animals.

**Winter Oats** have succeeded in some parts of the South, but are not a safe crop for the North. The seed is sown next month, but the preparation for it is now made, and the more thorough the better.

**Swamp Lands.**—This month and the next are the best for cleaning up the wet, low lands. The thick growth of grass and weeds is first to be cut and burned, when the soil will be ready to break up with a plow. So soon as the soil has been made fine by thorough harrowing, it should be sown to grass seed. Frequently it will be necessary to run one or more

**Drains** before the soil is prepared for the seeding. During dry weather drains can be dug at much less expense than when the soil is full of water. In making a drain, it must be remembered that its value largely depends upon the thoroughness with which the work is done. A drain to be a paying investment must be a permanent improvement. It is better to make a single drain that will last than a larger number, with the same money, that are imperfect, and will be constant sources of trouble.

**Muck.**—This valuable material for the barn-yard, stable, and compost heap, can be dug with greatest ease and profit at this season. It may be drawn out into a heap near by, with a team and a dump scraper, where it can get dried out, and afterwards be drawn to the place where it is to be used.

**Composts.**—There are many waste matters about the farm, and they should be gathered into a heap, and there rotted into a valuable fertilizer. Weeds of all kinds that do not contain ripe seeds, and refuse of crops, should go into the compost heap.

**Fall Fallowing.**—It is wise to plow as much as possible for spring sowing. It is a half-way fallowing, and in so far an advantage to the soil; it is of more benefit to heavy land than light, and the earlier it is done the better. Fall plowing greatly facilitates the farm operations in the spring.

**Mangels and Beets.**—The root crops need frequent cultivation through August, and as long as the foliage will allow it. Sugar-beets are best if earthed up until the roots are entirely below the surface. Mangels do not require this care in “hilling up.”

**Potatoes** should be harvested so soon as they are ripe, otherwise the tubers may sprout, especially if the weather is wet; they are more apt to be affected with the rot if not removed from the soil as soon as they are mature. Burn the vines.

**Cows** will need some fresh fodder when the pastures become short and dry. Fodder corn is excellent for this, keeping up the flow of milk through the season. An abundance of cool, fresh water ought to be within the reach of the cows, and also shade from the hot sun of the summer noon-day.

**Sheep.**—The coupling season begins soon, and a good ram only should be used. If possible, secure a pure blood—a poor ram is poor economy. The

**Lambs** should be separated from the dams and given a good pasture by themselves. If early lambs are desired for the spring market, a Southdown cross is preferable for quality, though in size the Cotswolds are much larger than the Southdowns.

**Swine.**—By proper management two litters of

pigs may be obtained from the same sow in a year, and with considerable profit. It is frequently an advantage to have pigs come in August, as they can then be ready as small pork for the holidays. Above all, keep the pens neat and clean.

**Horses.**—Pasture alone will not be enough for horses at night that are kept at work through the day. A run in the pasture will be beneficial, but a feed of grain should be given before being turned out. Work horses plowing on hot, dry ground are subject to brittle hoofs; this may be remedied by keeping the hoofs soft by an occasional application of glycerine. The shoes should not be kept on too long, otherwise the hoof growth will not be natural.

**Clover Seed.**—Clover cut early for hay will be ready to cut again for seed this month. The sod may be turned for wheat, and will furnish a large amount of valuable quick-acting plant-food.

**Gas Lime,** when it can be obtained for the trouble of drawing it away, is worth all it costs. It should not be used fresh, but put in heaps ready for spreading on the land in the spring. In a few months the injurious gases escape, and it becomes a mixture of various compounds of Lime.

**Poultry.**—The value of pure bloods is now well established. This month is a good time to clear out the old mixed fowls and procure a few specimens of one of the best sorts; both the pleasure and profit of poultry raising will be increased by raising some one or more of the select breed.

### Notes on Orchard and Garden Work.

What was said in this place last month, on the need of more frequent intercourse between cultivators is still timely. The season of Fairs is so near at hand that the matter should be thought about and discussed. Fairs are so numerous and communication so ready that one can, by a little forethought, attend several of these gatherings. Be sure to do all that is possible to make the local fair attractive, and do not refrain from exhibiting because you think some one else may show something better of the kind. Show the best you have, and if another does better, try and learn how he did it. If a premium is awarded you for any article, no matter if it is only 25c., be sure and take that money. One way to destroy interest in a fair is for the few who think that they can afford to do so, to treat the awards as if they were of no consequence. If the fair is well attended by fruit growers, or those engaged in gardening of any kind, try to get up a meeting of such persons for an hour or so, for discussion and interchange of experience. A beginning, however small, in this direction, may lead to excellent results hereafter. This is but one of several methods by which even a small fair may be made an occasion of real interest.

### Orchard and Nursery.

It is now the time of year when returns are coming in for the work of the earlier portion of the season—the early apples, pears, etc., are ready for market. If one with fruit to sell could visit the city markets, he would learn by observation the importance of what seem to be trifles. It will not take long to learn that much depends upon a careful

**Sorting of the Fruit.**—At least three grades should be made, the "Extra," "No. 1," and a third sort, which in most cases, unless the fruit is very scarce, should not reach the market. Usually it does not pay to market the fruit as it comes from the tree—the greater the uniformity of the fruit all through the package the better it is for the producer.

**Packages.**—Very much depends upon the way the fruit is put up for the market—the size and shape of the packages, that they may be easily handled. The neatness of the package, with a plain label, goes far to secure the best prices at the market. Half-barrels, crates, and baskets, are the packages most used for early apples and pears and the last two for peaches. Whichever of these is used, the fruit should be packed in firmly to avoid the bruising that would otherwise follow from shaking.

**Peaches** require judgment in picking: the longer the time before they will reach the consumer the

harder they should be. A single over-ripe peach in a crate spoils the looks of the whole package, and though the fruit in the main may be first-class or "extra," it can only pass for poor. The poor specimens are as the weak links in the chain by which the value of the whole is estimated.

**Pickers.**—Persons who care nothing for the trees, and so tear and break the limbs that they look as if a hail storm had visited the region, are not fit to have in an orchard. It must be remembered that there are seasons to follow, and the trees should be treated with care accordingly; only the careful pickers are profitable pickers.

**Early Pears** require more care than other fruits, as they ripen and decay so quickly. They must be picked before they become at all mellow, and marketed at once. If for home use, they are best picked early and ripened in the house.

**Budding.**—So soon as the bark of the stock will raise easily, and the buds are mature, the budding may be done. A sharp knife with a thin blade, and the inner bark of the Basswood in thin strips for tying in the buds, are needed. Success depends upon having the bud fit closely to the stock, and this must be kept in mind in tying them with the bast.

**How to Bud.**—In the Notes for August, 1877, we gave full directions, with illustrations, of the process, which will guide any intelligent person in the work. As we can not repeat every year, this number can be had, by those desiring it, for 15 cents.

**Seedlings,** of evergreens especially, require shade during the hot weather. Leafy branches of trees will serve this purpose if nothing else is at hand.

**Young Trees** require a mulch at this time to protect them from drying out at the roots.

**Insects.**—The "worms" of the Codling Moth are now in the "windfall" apples, and they should be fed to the hogs. The bands upon the trunks of the trees, as mentioned last month, will need to be looked to once a week and the "worms" killed. For treatment of Borers, see Notes for July.

### The Fruit Garden.

**Blackberries** for the market should be picked before they are fully ripe—for home use they may remain on the canes until dead ripe. The new shoots for next year's fruit having been selected, the rest of the suckers should be treated as weeds, and the old ones cleared away so soon as the fruit is off. The young canes should be stopped by pinching at the height of 6 feet, or even lower, that branched and stocky plants may be secured. Three or four such canes are enough for each stool.

**Raspberries** will need much the same treatment as the blackberries. Pinch back young canes to 4 feet or less; clear out old ones after bearing.

**Grape Vines.**—If mildew makes its appearance, the vines should receive a thorough dusting of Sulphur at frequent intervals until it is subdued. A still morning is the best time to do the dusting, using a bellows to throw the sulphur on to the under-side of the leaves. The presence of mildew is known by the white spots which it makes on the leaves, and afterwards, if not attended to, upon the clusters of fruit. Pinch back *lateral*s, as directed in previous Notes.

**Insects** of whatever injurious kinds, will have to be fought. The large caterpillars and beetles on grape vines are best destroyed by hand-picking.

**Strawberries.**—Early formed plants from runners rooted in pots, may be expected to bear a good crop next year. Ordinary plants set in the ordinary way this fall may give a few berries next season, but not a full crop until the year following. The old beds should be well manured and kept clean of weeds.

### Kitchen and Market Garden.

Weed killing will still be required, though most of the crops are beyond injury from them. A weed that goes to seed now—and they do very rapidly—means a full supply of young plants to stock the ground for another season. If the crop is removed from any portion of the garden, an occasional run of the cultivator over it will keep the weeds down, and at the same time improve the soil. It is better to sow such places with some late crop, such as

**Spinach, Late Turnips.**—Spinach to be wintered should not be sown until next month. "Yellow Stone" and "Aberdeen" are good turnips to sow now; the Strap-leaf will do if sown next month.

**Beans.**—It is not well to hoe beans when the vines are wet, as it is said to make them rust. For pickling or salting, the "Refugee" is best. Sow "Early Valentine" for a late crop of snaps. The stems of Limas need pinching off when at the top of the poles.

**Beets** need frequent hoeing and thinning. Use the young plants for greens.

**Cabbage and Cauliflower.**—Set for late use. The "worms" are best removed by using hot water (180°), sprinkled over the plants through a fine rose.

**Carrots** to do well require clean culture. When too large to hoe, pull the weeds that show themselves.

**Celery** should be set out at once, and in well manured moist soil. Hoe earlier plantings frequently.

**Corn** for late crop should have the soil kept open, mellow, and free from weeds. So soon as the ears are picked the stalks may be cut and fed to the cows or other stock, or cured for winter.

**Cucumbers.**—The soil should be cultivated so long as the vines will allow of it, after which hand-pull the weeds. Gather the fruit for pickles when of the size of the fore-finger—some prefer them smaller. Always cut with the stem left on.

**Egg Plants.**—Keep clean of weeds, and place straw under the fruit to keep them from the ground.

**Melons.**—The late sets will not mature; therefore pick them off, that all the nourishment may go to the earlier ones. A mulch of straw just before the vines begin to run will keep the fruit from the ground. A more uniform ripening is secured by occasionally turning the fruit when near maturity.

**Onions.**—Harvest the crop so soon as the tops die, and after being well dried, store in an airy place.

**Potatoes** should be dug so soon as ripe, which is known by the dying down of the vines. Clean the ground of all weeds.

**Seeds.**—In a small garden where there are several varieties of one vegetable, it is almost impossible to keep the kinds distinct, and as a general thing it is better to buy seeds of those who make a business of growing them. If any are to be saved, let it be from the best and earliest.

**Squashes.**—Pull out the large weeds after hoeing is over; and watch for any injurious insects.

**Sweet Potatoes.**—Vines should not root at the joints, as small potatoes form there at the expense of the large ones. Move the vines when hoeing.

**Tomatoes.**—A cheap frame of some sort should be provided to support the vine and keep the fruit from the ground; if nothing better is provided, use brush or straw for the fruit to rest upon.

### Flower Garden and Lawn.

In a dry time it is well not to commence watering unless it can be done thoroughly and copiously; a mere sprinkling of the foliage does but little good. Where a general watering is not practicable, those plants that seem to suffer most should have the surface earth drawn away, the ground well soaked, and then the dry earth returned. The neatness of the beds will depend largely upon careful trimming and pinching, especially if designs are attempted in foliage plants. The lawn will need the weekly visit of the lawn mower.

**Dahlias, Tuberoses, Gladioluses, etc.,** will need stakes for the support of their flower stalks.

**Large Weeds** in the lawn are best removed root and all by using an old chisel fixed to a handle.

**Walks and Drives** need to be raked occasionally, and the edges trimmed to look neat and clean.

### Greenhouse and Window Plants.

Whatever repairs are needed about the greenhouse should be made before the time for taking in the plants. The heating apparatus should be looked to that it may be all right when needed. The wood-work of the houses should be thoroughly washed; and a supply of pots, labels, potting material, etc., provided before the busy days of autumn are at hand. The propagation of many plants for winter may be going on, that a good stock may be in readiness for decoration of the house.

## The Compound Microscope—Answers to Questions.

In several hundred letters recently received are numerous queries which are mainly answered by the following: The "magnifying power" of a Simple or Compound Microscope is usually stated in *diameters*, that is, the increased size shown in *one* direction. For example, a small dot (fig. 1), seen in an instrument magnifying only 10 diameters, is stretched out one way as seen in fig. 2. But it is magnified in every other direction just as much, as shown in fig. 3. That is, its area or surface would be seen covering about 78 times as much space, while a small object seen through a microscope magnifying 100 diameters, would cover a space over 7,800 times as great as the object itself. This of course brings out many thousands of points, lines, and parts, too small to be seen by the unaided eye. (The *American Agriculturist* Compound Microscope, by the use of single and double lenses and the draw-tube, can be arranged to magnify all the way from 25 diameters up to 150 or more, and works very clearly for 125 diameters, which is equivalent to magnifying the area or surface over **12,000 times!**

The power and definition of this instrument is sufficient for all ordinary uses of amateurs and professional men. Those desiring higher power for special scientific investigation, can be supplied with achromatic "French Trip-let" lenses, having screws to fit this instrument, and of almost any power desired, up to 300 or 400 diameters or more, at a cost of \$3 to \$10, according to the special power desired.

This Microscope has a concave mirror, on a movable arm, allowing it to be turned *under* the stage to concentrate light under or through transparent objects; or at one side *above* to throw light down upon opaque objects.

The *Camera Lucida*.—The long-known *Camera Obscura* is an arrangement for throwing an exact image of an object upon a screen in a *dark* room (*obscura*). The *Camera Lucida* (light) is an attachment to the eye-piece of the Microscope, which throws the magnified image of an object upon a partially lighted screen or paper, so that one can see it well enough to run a pencil over it, and thus make a picture of the magnified object for preservation. This requires only skill enough to pass a pencil over the picture as it shows on the paper. Until the production of this new Microscope, any *Camera Lucida* attachment for the Microscopes in use, alone cost more than this entire instrument, camera included.

The regular retail price of the *American Agriculturist* Compound Microscope is \$15, which is less than half the price of any equally powerful and convenient Microscope previously offered in this country. But it was devised wholly in the interest of the readers of this Journal, and it is supplied to any actual subscriber for \$10—or given as a Premium for *Ten* annual subscriptions at the regular rate of \$1.50 each.

It has received the highest commendations of many scientific men, as well as many hundreds of our lay readers. (Some of them are given in our pages for June, last year. Prof. Spencer F. Baird, Secretary of the Smithsonian Institution, at Washington, uses one, and has sent many persons to us to obtain them, though by his official position he is precluded from giving a written recommendation of it, as he would otherwise gladly do.)

Other questions received are all answered, we believe, in the illustrated description which is sent to applicants.

**Soil Exhaustion.**—Dr. J. B. Lawes gives some important notes on the exhaustion of soil as deduced from his famous field experiments. He writes: "It is now exactly forty years since we began to exhaust a portion of one of my fields by continuous unmanured wheat crops; it may therefore be interesting to show the evidence we are in a position to bring forward upon the subject of exhaustion as regards the soil at Rothamsted....

The annual decline due to this cause may amount from one-quarter to one-third of a bushel of wheat per acre per annum. If we take the smaller quantity, and add to it the ordinary proportion of straw, the result would be equivalent to about forty pounds of produce.... The amount of matter annually taken from the soil by this forty pounds of produce, including the nitrogen it contains, would be between two and three pounds. The evidence derived from other experiments in the same field, proves that the decline in produce is due to an absence of nitrogen, as also that the minerals are in excess, but the actual amount of nitrogen that this forty pounds of produce would have contained, would be less than one-half pound in weight." This seems like a small matter upon an acre of land, but it is to be observed that in forty years this annual decline amounts to ten bushels of grain. Dr. Lawes concludes that "the gradual decline in the produce is due to the diminishing amount of nitrogen in the soil. It is also evident that the source from which the forty crops obtained their supply must have been the stores of nitrogen already existing in the soil when the experiment commenced; further, it seems most probable that the yield of future crops will depend upon the amount of nitrogen liberated each year from the soil." It is through such long extended and carefully conducted experiments as these of Dr. Lawes that we are to learn the nature of soils, their exhaustion, etc.

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**Reliable Business Men**, those who have both the *ability* and the *intention* to do what they promise, are the *only* ones invited to use the business-pages of this journal, and those in charge of that department are under positive instructions to admit no others at any price; and they try to live up to it, and generally do, though once in a while they may make a mistake—to err is human—but this seldom occurs. We could make a fortune in a single year, and supply the paper at lower rates, if the advertising pages were thrown open to those who gladly pay high prices, as they can afford to, because they give little for much. But we mean our advertising pages shall be a valuable source of *trustworthy information* to our readers.—When ordering from, or corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**Attending the Fair.**—It will soon be "fair time," and already preparations should be in progress for both attending and making exhibits at one or more of them. There are many reasons why the farmer and family should attend the fairs. It is a source of both instruction and amusement to old and young. Many a lad has had his interest kindled for improved machinery, live stock, fruits, etc., by attending the fair.

**What is the Use?**—If "J. B. H.," of New Holland, Ohio, had signed his full name, he might long ago have had an answer by postal card—telling him that there were probably no Cashmere Goats in the country.—There was nothing in the question that "J. B. H." need be ashamed of; even were he candidate for President, no capital could be made against him. What is the use of writing letters and omitting to sign them? The general fate of such is the waste-paper basket. If a letter is not of sufficient importance for the writer to sign it, it is of no sort of importance to us, and three cents may be saved if the writer puts it into his own waste-basket.

**Drink for Hot Weather.**—In England, and largely elsewhere, a drink is made by mixing oatmeal with water, three or four ounces to a gallon. It is found to satisfy the thirst as well, if not better, than pure water. The oatmeal is a nutritious food, and when taken with the water, while it is pleasant to the taste, the mixture makes a "victuals and drink" that is commendable. We like it, and have taken many a drink of it in the hay-field, or while hoeing the corn, etc. The Mexicans use upon long journeys, and herdsmen and the poorer laborers live upon, a food called *Pinole* (pronounced pin-o-lee, with the accent upon the o). Corn is parched, or roasted (not popped) and ground into meal, sufficient sugar is added to pleasantly sweeten it, and cinnamon or other spice is often used to give a pleasant flavor. In this the grain is thoroughly cooked, and only needs to be mixed with water, and one has a hearty meal ready at once. It is mixed with water sufficient to form a mush, or it may be used with a larger quantity of water, to form a gruel, which we know to be a most refreshing drink.

**Sorrel.**—"P. R. H.," Summit Co., O., asks how to exterminate Sorrel. He says that some in his vicinity say that it is due to "sourness in the atmosphere." We have often heard it ascribed to a sour soil, but not before to a "sour atmosphere." The best way to get rid of sorrel is to improve the soil, and encourage the growth of grass to crowd it out. The idea that Sorrel, or any other plant, can take up acidity from the soil is erroneous. Sorrel and Sugar-beet, grown side by side, will be sour in one case, and sweet in the other. Both the acid and sugar are formed in the plant, not taken up by it.

**Great Increase of Immigration.**—A circular issued by the Bureau of Statistics at Washington, shows that the number of immigrants arrived in New York for the year ending May 31st, 1879, was 92,351. The number for the year ending May 31st, 1880—236,017.

**Blossoms, but does not Bear.**—Every now and then some one asks what can be done with a grapevine that flowers freely, but will not bear a cluster. Either graft a good kind upon the root, or set out another to take its place. Some vines are imperfect in their flowers, and nothing will make such produce fruit.

**The American Association for the Advancement of Science.**—"What's in a name?" Had the poet asked with reference to this one, the correct answer would have been—four dozen letters. The Society must have more than usual vitality, as it has carried that name about the country for over 28 years, and will hold its 29th meeting at Boston, on the 25th of the present month. The annual gatherings of this body of scientific workers are most pleasant occasions. Its members number nearly 1,000, and as those who attend are usually accompanied by their wives and daughters, the meetings are quite as social as scientific. Workers in every department of science get together once a year to tell what they have been doing. There is such a number that they divide up into several sections, so if one finds the doings in one section not to his taste, he can go to another. As the Association is hospitable to all listeners, our friends in Boston and vicinity, even if not members, will find the sessions, as a general thing, instructive and enjoyable. Boston is a capital place for such a gathering; its people are used to entertaining crowds, and know how to do it. F. W. Putnam, Salem, Mass., is Permanent Secretary, who will give all needed information to those intending to attend this interesting and instructive meeting.

**The Coming Fairs.**—Our Fair-List is made up largely from the announcements sent us by officers of the Societies holding them. A large number of premium lists and other announcements of Fairs have already been received and placed on file.—To the Secretaries of all others we would say, please send the *date* and *place* at once. The *State*, *County*, and *Town*, as well as the *date*, should be clearly and accurately given. Also the Secretary's P. O. address.

**Muck: Dig it Now.**—The dry weather which usually comes in late summer makes this a good time to get out a supply of muck. This valuable absorbent for liquid manures, when of the best quality, contains a large quantity of nitrogen, which, when decomposed in the compost heap, makes of itself a large amount of valuable plant food. As a source of manure, it is of importance.

**"What is This?"** is a question that is, of course, a familiar one to us. For example, it comes to our table together with an object which may be described in brief in something like this wise. It is about two and a half inches long, and half an inch in diameter, chestnut brown in color, round, tapering at both ends; from one end, the head, proceeds a long, curved proboscis, like a jing handle, while the opposite end is divided into a number of rings. It is alive, because it moves its ringed extremity when touched; but it is entirely helpless, for it goes without taking any food. This is the pupa, or chrysalis, of the "Tomato Worm" that is so destructive to the foliage of the tomato and several other plants. When the mature insect comes out of the pupa case it will be a large and handsome moth, of an ashen-gray color, with bright yellow spots on its body, and a very long tongue, which, when not in use, is coiled up under its head.

**"Pig in the Clover."**—A farm is not complete without pigs; and pigs are at their best in a field in which they have green food to pick, and a field is often the most profitable when it is growing a good crop of tender clover. The green food the pigs get acts as a corrective to their feed at the trough. Pigs that are getting clover or grass can be fed corn without the injury it would do them were they confined closely in pens and deprived of green food. When the grass is short, a feed of fodder corn is important, and especially so for sows that are rearing young pigs, as such green food increases the milk and keeps both sow and pigs in a healthy condition.

## Some Things this Number Contains.

The Hints for the Work on the Farm and in the Orchard and Garden, pages 294, 295, will aid all cultivators.

The Third Prize Essay on KEEPING ONE COW is of special value to our Southern readers, showing how much a half acre may be made to yield; pages 310-311.

The House Plan will meet the wants of many who live where they can get stone cheaply; page 304.

The Talk about "Patent Medicines," and the Quackery connected with them will interest many, and should be read by all; pages 300-301.

The Editorial Correspondence, pages 301, 302, 303, makes a valuable collection of suggestive items of information.

The Sheep Rot, and many Hints and Helps for Farmers, etc., pages 303 to 312.

Flowers, Plants, Insects, etc., pages 313-314-315.

The Famous Jersey Cow, "Eurolas," page 305, will interest the hundreds of thousands who have cows.

The Household contains a variety of information, including Faith Rochester's Notes; pages 316-317.

The Boys and Girls will read pages 318-320.

The Basket is large; pages 296 to 300, and 325 to 329.

**Crop Prospects.**—*Wheat*: Owing to the open winter much of the wheat was seriously injured, but the weather of early spring was in its favor. A large area of the winter-killed wheat in the Northwest was re-sown to spring wheat, which did very well. The increased acreage of wheat and its uniform good condition seems to indicate a crop exceeding the 440,000,000 bushels of last year. *Rye*: The acreage and yield are both larger. The poorer soils of New England, that do not give good crops of wheat, have produced a large yield of rye. *Barley*: The yield is reported good everywhere, and the crop may be expected to be in the neighborhood of 50,000,000 bushels. *Oats*: The yield will be heavy, and the acreage, especially in the Southern States, is far greater than in previous years. An aggregate crop of 450,000,000 may be expected. *Hay* is very light, owing to the dry weather that has so generally prevailed, and the price will be high. A substitute in fodder corn or Hungarian grass must help out in the winter feeding of stock. *Potatoes* are a fine crop; though the Beetles have been abundant, they are now so easily handled that potatoes are again one of the sure crops. *Fruits*: This is the bearing year for apples, and a good supply may be expected. Pears are a light crop; and peaches are not more than an average. Grapes are excellent.

**Excelsior for Packing Fruit.**—"Excelsior" is the trade name given to fine wood shavings, made originally, we believe for the use of upholsterers as a substitute for hair and other expensive materials, in stuffing mattresses, sofas, etc. It is elastic and perfectly cleanly, and if made of the proper woods free from odor. Such a material has naturally been found adapted to other than its original uses, and is now largely used for packing various small wares. The latest application we have noticed is in packing peaches. Peaches for a near market need no packing, but the growers in Georgia seem to think it necessary to use something with their fruit and have hit upon Excelsior. Whether it is necessary or not, the fruit packed in shallow crates, with a layer of Excelsior above and below them, reaches the market in as perfect condition as those from much nearer points.

**Coal Tar for Insects.**—"T. D. P.," Madison, Wis., initials that many will recognize as those of a well known pomologist, writes that he finds water impregnated with gas-tar a simple and sure remedy for the destruction of bugs and worms on all kinds of plants. He says "it should not be used too strong," and this leads us to ask him how we are to fix upon the proper strength.

**Gasoline, Naphtha, Benzine,** are names for very similar products obtained in refining petroleum. When crude petroleum is put into a still, and the heat gradually raised, that liquid which distills off at the temperature of 170° is called Gasoline; that which distills at 280° is Naphtha. The liquid which distills at 300° is Benzine, while properly prepared Kerosene distills only at 400°. Gasoline, Naphtha, and Benzine are very similar liquids, differing in their specific gravity and boiling points. There is a still more volatile liquid than Gasoline, obtained in small quantities, viz.: Rhigoline, which boils at 100° or less. As there is but a limited demand for these products in the arts they accumulate on the refiners' hands, and are sold at very low prices. There is a great temptation to unscrupulous retailers to buy these cheap products and mix them with kerosene; though the law has largely checked this adulteration, it is still more or less done in defiance of the law, and kerosene bought of unknown persons should always be tested before risking its use. These products, Gasoline, Naphtha, and

Benzine, have high illuminating and heating powers, and being also very cheap, it is natural that many attempts should be made to utilize them for lighting and as fuel—and various lamps and gas generators, as well as stoves, have been invented for the purpose. We have examined a great many of these, but have not only not seen one that we could commend, but we have refused to advertise them, as we regard all that we have examined as unsafe and their use attended with danger. The inventors show very clearly that no explosion can take place in their lamps or other apparatus, as they have guarded against this at every point. Still there remains the fact that their use requires the storing and handling of liquids that are unsafe in a high degree, and should never be trusted, as such things will be, in the hands of ordinary "help." The following is cut from the "N. Y. Evening Post" for May 26th last:—"Mrs. Frances Jones, of Piqua, O., had a barrel of gasoline in her cellar to be used as fuel for a gas stove. Yesterday morning the barrel seemed to be leaking, and F. W. Amendt, a neighboring grocer, and two boys named Perdue, about sixteen and twelve years old, respectively, went into the cellar to see what was the matter. One of them struck a light, and instantly an explosion occurred, which shattered the building from cellar to roof, and threw a mass of brick and shingles fifty feet in the air. The two Perdue boys, Mr. Amendt, and a lady in the house, received fatal injuries."—Such casualties occur every now and then, and so long as these articles are in use with the present means for keeping and handling them, they will continue to occur. The fact that such "accidents" are possible, seems to us sufficient to justify our position in relation to the articles and all contrivances for their use.

**Weights and Measures.**—R. Forest, Ont., Canada, thinking "we have much need of a change in our weights and measures, the present system being too complicated," sends us the system he proposes, and asks us to publish it, and invites those who differ from his views to discuss the matter with him in our columns. We must decline both to publish the system, and to give room for its discussion. When one takes up a subject of this kind, he should first learn what others have done before he proposes a method of his own. The subject has been thoroughly investigated and discussed, and systems vastly preferable to that of Mr. F. have been proposed. The trouble is not in the lack of better systems, but in the reluctance of people to make a change.

**Sending Fruits.**—A large share of the specimens of fruits sent each season for our inspection, are perfectly useless when they reach us. Fruit sent by mail in a paper box, if it is not thrown out by the way, is so badly bruised when it arrives as to be past recognition. Fruit by mail should be in a wooden or tin box, and so closed that it can be opened for inspection; nails, tacks, sealing wax or gum, subject the parcel to letter postage. Do not use a cigar or perfume box, or any other that will give the fruit an odor or flavor; do not use cotton for packing any soft fruits. In sending by express, pay charges in advance—we have done paying such.

**Fish Culture,** it has been supposed for years, would do for an amusement but not as a business except in a few rare cases. Very great progress has been made in the artificial growth of fish, largely through the exertions of the United States Fish Commission, which has, among other things, distributed, within the last year, a large number of the European Carp. We should be pleased to hear from some of those persons who have been most successful in the growth of this remarkable fish. Perhaps the California people can make as good a report as any—at least we infer it from the notes in the Pacific press.

**How Large a Grape Vine** can be moved with safety? asks "J. M. W." If the question refers to the safety of the vine, if well cut back, a vine as large around as one's arm may be moved and live, but it will be a very unprofitable job. If the writer would ask how large a one may be moved with profit, that will depend upon what kind of treatment it has had, and its present condition. As a general thing it rarely will pay to move an old vine. A new one is obtained so easily, will grow so rapidly, and in a few years be so much better than an old vine, that has been moved, that it is better to start anew.

**Questions about Grafting.**—"W." asks how large the cions used in grafting should be. The shoots of the previous season's growth are used, and these vary in size with the variety and the vigor of the tree from which they are cut. The average is about the size of a lead pencil, or somewhat smaller. He asks if more than two cions can be inserted, and how if but one should grow? In what is known as crown grafting, more than two can be put in, but it is rarely done. If but one of the cions should grow, remove the dead one. One, in a majority of cases, is enough, and where two grow it is often one too many.

## Interesting Figures.

Many unmathematical persons "hate figures," and hastily skip over any article or item that presents any array of them. But, very often, a few numbers stand for and represent great and important facts in the commercial and industrial prosperity of our country, and can but be of great interest to every one. The very condensed tables at the head of our Market Reports in every paper, give at one view the summary of an immense number of transactions in Breadstuffs. For example, this month we find the receipt, during 24 days, at the port of New York alone, of **14,867,000** (nearly fifteen Million) bushels of grain, reckoning each barrel of flour as five bushels of wheat, or 3,195,000 bushels more than during the same period last year.

But the SALES have been on a still greater scale. The summary of 24 days transactions show sales to the enormous amount of **36,969,000** bushels—a million and a half bushels for every day!

The Exports. The first line of table 4, shows that during the first half of this year, including eight business days in July, there have gone abroad from the New York port alone, an equivalent of no less than *Sixty-four Million* Bushels of grain. From Jan. 1, to July 9, 1880, the total exports from New York alone ran up to nearly a round **\$200,000,000** in value (\$199,704,348) and for the year ending July 1, 1880, the exports (from New York alone), reached **\$400,798,000**!—The exports for June amounted to \$43,084,568—the largest amount ever sent abroad in the history of the country, we believe, during one month. All the above figures will be greatly swelled when we get returns from Philadelphia, Baltimore, Boston, New Orleans, Charleston, San Francisco, and other shipping ports.

To help the conception, suppose the above 64,000,000 bushels of grain exported from New York this year up to July 9, had been brought here on wagons, 40 bushels to the two-horse load. Three million two hundred horses would have been required, and one million six hundred thousand drivers. These wagons arranged in a line, allowing 50 feet to each, for wagon, team, and headway, the line would extend **15,151** miles, or make up nearly five lines of teams all the way from the Atlantic to the Pacific Ocean.—Put 250 bushels of grain in each railway car, and allow only 30 feet to a car. To bring this 64 million bushels of grain would require a continuous freight train of 1,455 miles, allowing nothing for engines. This would closely cover a track from New York to Omaha, or about halfway across the Continent! Note that we only speak of exports of our surplus, and from New York alone, during six months. *This is allowing for only about one bushel out of every TWENTY bushels of corn and wheat grown in this country during 1879.*

### A FEW COMPARISONS.

Taking the Census Report of 1860, and comparing it with the estimates for the year just ended (July), we have the following figures, showing the wonderful expansion during the short period of 20 years, in our country:

	1860.	1880.
Corn produced, bushels.....	838,792,740	1,450,000,000
Wheat produced, bushels.....	173,104,924	440,000,000
Wool produced, pounds.....	60,264,913	232,500,000
Cotton produced, bales.....	4,823,770	5,675,000
Hogs packed, number.....	2,350,822	6,950,451
Iron produced, tons.....	919,770	3,070,875
Petroleum produced, barrels.....	500,000	19,741,661
Gold and Silver produced.....	\$46,150,000	\$79,711,990
Wheat exported, bushels.....	4,155,153	175,000,000
Corn exported, bushels.....	3,314,305	100,000,000
Butter exported, pounds.....	7,640,914	38,248,016
Cheese exported, pounds.....	15,515,799	141,654,474
Merchandise exported.....	\$316,242,423	\$835,000,000

**Canned Meat.**—During the hot weather many families experience considerable difficulty in keeping a supply of fresh meat. Without a refrigerator or an unusually cool cellar, meat will spoil in a very few hours. As a substitute, meat may now be bought in cans which may be opened at any time. The canned meat industry is now a very large one. It is estimated that fully three hundred thousand head of cattle are annually slaughtered in Chicago alone to supply the demand for canned meat.

## The Preservation of Corn Fodder in Silos.

Soon after the plan of preserving corn fodder in tanks or silos, was published in France, the *American Agriculturist* gave a full account of the matter, and reproduced the engravings of the structures used by the inventor. These will be found in June 1875; and in April 1879, we gave an engraving of a machine invented in this country for the wholesale cutting of the fodder. Besides there have appeared from time to time other articles upon the subject. The matter for two or three years appeared to receive but little attention on the part of our farmers, but since accounts of some successful operations in this country have been published, there is a widespread interest, and there is no subject upon which we have, just at present, more inquiries than those relating to this. "The Ensilage of Maize," which is very nearly the French name for the process, seems to be very generally adopted in this country. *Silo*, is the French word for a "pit,"—*Ensilage* means the putting into pits. As the pits are built above ground, they have been called "tanks," and we have known the "tanking of corn fodder," used to express the operation. In view of the general desire for information we will endeavor to present next month, the substance of what has already been given, and such other matter as will allow those who may wish to do so to experiment understandingly. The preservation of green fodder in a like manner is by no means new; clover has long been similarly stored, and so have beet leaves in the sugar-beet fields of Europe; in this country brewers' grains, and partially ripe Broom Corn seed have also been thus preserved. It is applying to the preservation of corn fodder the same principle that nearly every house-keeper makes use of in preserving fruits. Every one knows that if green corn fodder, or other green vegetable matter be placed in a heap, fermentation will take place and decay soon follow; fermentation and decay require the oxygen of the air; exclude the air and these must cease. In Ensilage the corn fodder is put away with the air excluded and it keeps. Every detail of the operation has for its object the thorough exclusion of the atmosphere; the silos, or tanks are tight; the fodder cut small, that it may lay more compactly, and great pressure put upon the mass, all for the purpose of keeping out the air as completely as possible. That the fodder thus put up will keep in excellent condition is an established fact; it has been kept thus not only through the winter, but throughout a whole year.

Do we advise farmers to put away their corn fodder in this manner? Yes and no, and mostly no. Dairy farmers who carry on business with a sufficient capital, may incur the necessary outlay with a prospect of a fair profit on the investment, and the same may be said of those farmers who carry a large number of animals and can afford to make the investment. But with the average farmer, the case is different. No half-way work will do, the silos must be air tight or their contents will spoil; a large mass of corn fodder must be cut fine, and all at once, and to do this requires an outlay for machinery and power, which most farmers cannot command. There must be a large number of animals to consume the fodder profitably, when a silo is opened and the contents exposed a change takes place, and the consumption must of necessity be rapid or there will be a loss. We look upon the process as one that, so far as the average farmer is concerned, has yet to be Americanized and adapted to his circumstances and needs, and it is in this direction that we would encourage experiment. For large operations the present methods answer; we now wish to have a process by which one who keeps from two to six cows can prepare his silos, or preserving receptacles, with but a moderate outlay for materials and with ordinary labor; and the process needs to be otherwise so modified that the cost of putting away his fodder by this method will not more than offset its advantages. That this may be accomplished is our sincere hope. But at present it will be a great step if the discussion of the matter leads farmers in general to make better use the means they have. But a small share of the labor required by Ensilage, applied to saving the fodder they already have, would re-

sult in great gain. Leaving the matter of fodder corn out of the case, the matter of corn fodder deserves far more consideration than many give it; in the cutting up of the corn at the proper time and the care of the stover after husking, there is abundant room for improvement.

**Yellows in the Peach.**—There is no remedy for the destructive disease known as "Yellows" in the peach tree. When a tree is once attacked it should be dug up and burned root and branch, otherwise the trouble will spread to other trees and in a short time the whole orchard is ruined.

**Entomologist for New York.**—The State of New York has at length a State Entomologist, Governor Cornell having recently given the appointment to Doctor Lintner of Albany. There was a movement on the part of some of the friends of Prof. C. V. Riley, now Chief of the U. S. Entomological Commission, to secure him as the New York Entomologist. Learning of this, Prof. R. wrote to Governor Cornell, declining to be considered as a candidate, and strongly urging the appointment of the present incumbent, Doctor Lintner. We are glad that this, which may be made one of the most important scientific positions in the country, is thus secured to a competent naturalist, and kept out of the hands of semi-scientific pretenders.

**The Farmer of the Future.**—Prof. Wrightson, in his inaugural lecture before the students of the Wilts and Hants Agricultural College, at Downton, near Salisbury (England) said, among other things, that: "The farmer of the future must then be a man of resource; he must be ready to adapt himself to new circumstances and to adopt new crops when he finds he is undersold. He must look upon the soil and air as his agents for the production of animal and vegetable forms, the precise type of which must depend upon the laws of supply and demand. If an ironmonger finds that he has a strong competitor in the sale of locks, he turns his attention to lamps or to something else, and so must the farmer."

## Sundry Humbugs.

In these days of summer showers and storms, accompanied by lightning and thunder, there cometh the Lightning-Rod Man. Other humbugs come and go; other frauds become known and cease to be profitable, but the Lightning-rod swindle is perennial. People are most easily humbugged in matters about which they know least; there is scarcely any thing—if we may call it a thing—of which there is so little accurate popular knowledge, as electricity. It is true that to the best informed there is much about electricity that is obscure, but its important facts and laws may be easily understood, and it is a great pity that they are not generally known. A lack of this knowledge in the community allows various electrical humbugs to succeed, from the ridiculous little so-called Batteries we recently exposed, up to the ubiquitous lightning-rod man.

### THE LIGHTNING-ROD SWINDLE

has two principal features. The lack of a knowledge of a few simple facts in electricity, allows the so-called agent to make people believe that safety lies only in using his particular style of rod—usually some outlandish "doubled and twisted" much insulated and variously be-painted affair that makes a house look somewhat like a gigantic hatchel, if one is so unfortunate as to allow the thing to be put up. The other feature is, that it is usually made the medium of some form of down-right fraud. Fraud in the price, in the measurement, in getting the victim under some pretence to sign a bogus note; frauds which, we are sorry to say, are by no means confined to lightning-rod men, but very often practised by them. These fellows are masters of their art; their

### KNOWLEDGE OF HUMAN NATURE

is so acute, their powers of illustration so great, and their glibness of tongue so remarkable, that one can not help wishing that their talents were exercised in some honest calling. With the majority of people, their only safety is in not listening to these chaps. If allowed to tell their story, they will convince most persons that they live in imminent danger; if the house has safely stood for 50 years without a lightning-rod, they can prove that the danger is all the greater; they can prove that a rod is needed then and there, and that the only rod that can possibly protect a house is the particular rod for which

they are agents. If one's house is already rod-d, however it may be with lightning, it is no protection from the lightning rod-d. The chaps will show very plainly that a house with the style of lightning-rod it happens to have, is just a trifle more unsafe than if it had no rods at all, and of course safety is only to be secured by

### TAKING DOWN THE OLD AND PUTTING UP THE NEW.

An allowance may be made for the old rod—which will straightway become a good one to be put up somewhere else! These chaps consider themselves in luck if on their first visit the man of the house is away, and they can operate upon the fears of the women. The various forms of swindling in measurement, etc., can as a general thing only be practised if the fellows are engaged to "rod the house," and our advice is to avoid these by having nothing to do with these travelling agents or their wares.... But what shall those who fear danger from lightning do? it will be asked. We present some suggestions to meet the case in an article given elsewhere.... As the so-called medical batteries profess to deal with

### LIGHTNING IN ANOTHER FORM,

we may say, as not foreign to the subject, that the battery business seems to be on the wane, only one new one having come before us since we last noticed them. Such a thing could not last long, it having no real value. Were the simplest laws of electricity generally known, these so-called batteries could deceive no one, as a glance at them would show them to be utterly worthless as generators of electricity.

### THAT SECRET SERVICE SHOP

at Cincinnati seems to have found business dull and in order to get its name before the public instituted a murder—on paper. Indeed so quiet had it been for a few months, that we had nearly forgotten it, but the Texas papers and a letter from an indignant reader in Texas, brought them to mind again. The "Galveston Daily News" published with the neat and taking little title of "A Hellish Crime," a telegraphic dispatch from Dallas, giving the story that two women disguised as men had cut the throat of a farmer's wife and that the women aforesaid were shot dead by a stranger. The dispatch took pains to state that the information was derived from the special agent of the Cincinnati Secret Service Shop. Two days later the "News" announced that the story was "untrue in every allegation and particular." Our correspondents feel justly indignant that these "Cincinnati frauds," in order to secure notoriety, by making it appear that their detectives discovered this remarkable crime, should select Texas as the scene of the exploit, though he regards it as a shrewd advertising dodge. Knowing that the "Hellish Crime" will be widely copied, while its denial will not be, and as one who has the interests of the State at heart he sharply protests against the course of the Secret Servicibles.... It has been before stated that the most annoying cases, we have to deal with are those in which we feel quite sure a scheme is a humbug, but have not the proofs to enable us to say so. As an illustration of this, and also as a sample of what is a frequent occurrence in our office, we give our experience with

### "THE CHICHESTER RIFLE"

which was recently advertised very largely through the country. As there are a number of better class journals which consider the admission of an advertisement in the *American Agriculturist* as a proof of its being worthy of a place in their columns, extraordinary efforts are often put forth to get such advertisements into our columns. Perhaps on this account, the "Chichester Rifle Company" made an offer of a liberal cash contract for their advertisement in this paper, amounting to several hundreds of dollars (to run to \$1,000 or more we believe). To get around our well known strict rules, the guarantee of \$10,000 from a well known respectable party was offered us that the said Company would do by our readers "just what their advertisement promised." The gentlemen in charge of our business columns, as in duty bound, and according to custom, submitted the matter to the Editor. It seemed to be "all on the square," but to be certain, we sent for one of the "\$4.50 rifles." On examination it proved to be a pretty good revolver, a 7-shooter, of 22/100 calibre (ball about the size of small buckshot). But the barrel was extended to 16 inches, with good sights, and a wooden, removable shoulder piece was attached to the breech for holding it steady. Well, here was a small repeating rifle, that would not be very dear at \$4.50 to any one wishing such a weapon for shooting at a target at short range, for killing rats, perhaps squirrels and other small game, at near distances. With such a "guarantee" should we not insert the advertisement? We first said yes, but on examining the large, page-wide advertisement, there was a lively and striking scene, well calculated to attract general attention. There was a combined prairie, mountain and forest panorama, with deer and other large animals scattered round, some alive and others shot down, and there were the hunters with their \$4.50 rifles doing it, while in the foreground stood out in large figures "\$4.50."

The impression to be conveyed was that the \$4.50 repeating rifles would be forwarded to hunt large animals, and shoot them at long distances, whereas a  $\frac{22}{100}$  bullet would only seriously affect a deer when chancing to strike a very vital part, and then at not over 50 or 100 yards. It was argued to us that "the picture was only to attract attention, and that the text of the advertisement did not actually promise any such results." But it did not say anything to the contrary, and so we felt compelled to reject the advertisement, in the interest of our readers, however convenient the \$1,000 proposed to us for a few insertions.—Afterwards it was again pressed upon us with the offer to strike out the prominent "\$4.50" in the engraving, and to make any other change we desired. This seemed fair, but reserving a little time to decide, we despatched a private "detective" to the advertised headquarters of the Company, in a neighboring city, who was instructed to go as a country purchaser of the rifles. He found instead of a large Arms Manufactory, with extensive offices, etc., only two small 3d-story rooms and a few of the "rifles" in a case on a small counter. That of course ended further advertising negotiations, just as similar investigations often do. We were saved the mortification experienced by many respectable contemporaries who adorned their pages with the big "Hunting Scene." They got their money; we suppose their readers got the wonderful \$4.50 repeating rifles; though for some reasons, not our fault, complaints came to this office that money had been sent and no rifle received; or, instead, in some cases at least, a postal had been received stating: "Order placed on file, and will be shipped when reached, not later than—," having a date two weeks or more ahead.—Result: we don't know how many of these "rifles" went out, or "went off," but the Company has!—(We can hardly wonder that a business man in Walla-Walla, a twenty years' subscriber, who depends largely on buying in eastern cities, should, in renewing his subscription recently, write us thus: "I consider the *American Agriculturist* of great value to me on account of its care over its advertising columns; I prefer, as a rule, to pay a double price for any article I want, if it has even the qualified endorsement of being advertised in your Journal.")

#### SUPPRESSING QUACK DOCTORS.

A large number of men, and some women, hang out their signs as "Doctors" or "Physicians," who are utterly incompetent to give medical advice. The mass of people have no means of distinguishing between these quacks and the really competent physician who has thoroughly prepared himself by studying, and by working under and with a regular practitioner. So, those needing or thinking they need medical advice, are just as likely to call upon one of these quacks as upon a trustworthy physician, or rather more so, as the former usually puts out the boldest, most attractive "sign." The regular physicians are limited by the rules of the profession from displaying any thing more than their full name and a single word indicating their calling.—The last Legislature of New York State made an admirable move towards suppressing this dangerous nuisance, in the passage of a law requiring every one offering to practice physic, medicine, or surgery, to be at least 21 years old, and to register before Oct. 1, 1880, in the County Clerk's Office, his name, residence, and authority for practicing, and receive a license. Persons coming from out of the State, to obtain a license, must exhibit a diploma of graduation from a reputable medical college.—Any person practicing without such license will be guilty of a misdemeanor, and subject to punishment by fine or imprisonment. Half the fines go the informer, and half to the county treasury. Now let not only the medical profession, but all good citizens, see to it that the provisions of the law are rigidly enforced, and let every State that has not done so, immediately enact similar laws, and one large source of swindling, of suffering, of death even, will be dried up. Let the good work be followed by other laws in regard to patent medicines. The necessity of such laws will be seen in an article on page 300.

**Harness Sores on Horses.**—There are few things which cause more delay and trouble in farm work during these hot months of summer, than the galls and sores that come upon the shoulders and backs of work horses. A vast amount of hard work must be done, and the animals are strong and well enough to do it, provided there were not these painful sores that prevent their applying themselves to the labor. A horse with shoulder or back galls, or both, suffers pain when it is put into the harness. The direct cause of these sores is the friction to which the parts are subjected, combined with the excessive heat and great flow of sweat. Inflammation and chafing of the skin are produced much more readily in hot than in cold weather, because the conditions of greater friction are then present. The preventive is in reducing the friction to the least possible amount. In the first place, the harness must fit closely and smoothly to the form of the horse, that the weight of the load

may be uniformly distributed over the surface beneath the harness. Secondly, the horse should be in a healthy state, that the muscles and skin may be of their normal toughness, and the sweating not unnaturally profuse. This involves the proper care and feeding of the horse. A poorly kept animal, or one not in good health, will become sore more readily than one in good health. When the sores are already formed, a speedy cure is the thing needed. Sponge carefully the afflicted parts, to remove all accumulations from sweat. Then bathe with a lotion of Alum and Tannin, with a little Laudanum added. All pressure upon the sore should be removed by a proper adjustment of the harness, and, if necessary, keep the horse from work until cured.

**Subsoiling.**—The advocates of deep plowing are not either so numerous or so strong in their views as they were a number of years ago. It is safe to say that one of the best methods of loosening up the subsoil—and this is the chief end to be accomplished in using a subsoil plow—is by deep running clover roots. With an occasional crop of clover that will send its roots below the depth to which the subsoil plow goes, the soil in most cases will be made deep and mellow, and at the same time enriched for the crop to follow.

**America at the Great Fishery Exhibition.**—The Fishery Exhibition recently closed in Berlin (Germany) was made a great success, largely through the American contributions—a fact most freely acknowledged by the German officials, and abundantly testified by the numerous awards made to America and Americans. The exhibition made by the U. S. Commission of Fish and Fisheries, of which Prof. S. F. Baird is the Commissioner, was at the same time the chief American contribution and the principal feature of the Fair. This was in the personal charge of Prof. G. Brown Goode, the competent assistant of the Commission, whose efficiency is testified to by all accounts of the exhibition and by a special award of a silver medal by the Crown Prince. America is honored, in the person of Prof. Baird, by the Emperor's prize, a gold and silver fish basin of elaborate design; and the various individual American exhibitors received prizes, so that in all no less than sixty honors of various kinds come to the United States. As this is the first International Exhibition in which this country has occupied the leading place, it is well to remember that it is due to competent management. Our former displays, however valuable individually, have been without arrangement and without a proper head. In this case, Prof. Baird officially and Prof. Goode personally so systematized the American display that America at once took the leading position that belonged to her.

**Granaries.**—In many cases it is the most economical to thresh the grain as it is drawn from the field. The straw being moved away in the barn in the space that would otherwise be taken by the sheaves before threshing. But as the grain is the chief portion of the crop, a place to store it must be provided in the barn, or other farm building. When the grain is threshed directly from the field it is green, and goes through a "sweating" process which, as heat is generated, may injure it, unless the bin is properly ventilated. To turn the grain in the bin by hand is hard work, and to obviate this, ventilating shafts should be made for the thorough circulation of air. These ventilators may be made of strips of half-inch

VENTILATOR FOR GRAIN BIN.

boards of convenient width, about four inches being usual, these are nailed together so as to form a triangular trough as shown in the engraving. The sides of the ventilator are bored full of small holes, and the ends coming through the sides of the bin are covered with a fine gauze. These ventilators are fitted into the bin, running from the front to the rear, with the open side downward. As the grain is poured in, a considerable vacant space is left below the ventilator, in which the moist and warm air can accumulate and then pass out the end of the ventilator. In this way, with two or three such ventilators in an average sized grain bin, even newly threshed buckwheat, the most "heating" of grains, may be stored without danger from overheating.

**The Ox-Eye Daisy.**—A Boston daily paper says: "The Ox-Eye Daisy has become a great pest in some sections of the country. Those who are troubled with this weed should bear in mind that it is propagated by seed and not by root, and that to rid themselves of it they have only to mow before the seed is ripe. It may take two or three seasons to rid a field of this innocent-looking flower."—This is an "innocent-looking" paragraph, but calculated to do mischief. The writer has somehow got hold of the idea that Ox-Eye Daisy is an

annual, while it is really a perennial and *does* spread by the root very freely, and is also propagated by seeds. As with other perennial weeds, it should be cut while in flower to prevent it from ripening seeds. Mowing at this time will tend to weaken the root, but it is only through frequent and persistent cutting that it can be subdued.

**News from Cloudland.**—Not a spiritualistic revelation through a "medium," but a very matter of fact communication from a scientific gentleman who is in the mountains of North Carolina on a tour of observation. Cloudland is on Roan Mountain and 6,367 feet above the sea level. On a day in the middle of July, with the thermometer in the nineties in the city, it is pleasant to read: "It is simply glorious. In ten days our extremes of heat have been 50° and 67°, air bracing, water crystal, views magnificent; for we can see land in seven different States. The show of *Rhododendron Catawbiense*, when the whole mountain was one great dome of flowers, was indescribably beautiful, while *Azalea calendulacea*, with its masses of flame, is worth coming here to see."

**A Very Curious Growth.**—Many articles are sent us which are simply curious or unusual, but which teach no especially instructive lesson. Of this kind is the specimen forwarded by W. J. Hester, McLean Co., Ill., which consists of two seedling Osage Orange plants, which are put together much as a blacksmith would arrange the parts of a pair of tongs. A root in its forward growth exercises a surprising amount of force, and we have seen various cases in which a soft and apparently yielding mass has moved a great weight for a very short distance. We have frequently seen cases in which roots having met with a potato, or with a beet or other root in their course, have pierced and gone through the obstacle, instead of going around it, as they would have done had it been a stone. All that can be said of the present case, of which we figure the interesting portion, is, that the point of one root pierced the other root when that was young and soft, and in their after-growth the two roots accommodated themselves to the situation.

**Refrigerators.**—"L. B." In the June number of the *American Agriculturist*, 1875, a Home Made Refrigerator is illustrated and described. An ice-box of this kind which will answer all the purposes of a more costly refrigerator for a small family, can be made with very little outlay of time and money. An ice-box can be made from two dry-goods, or other boxes, the one smaller and put within the other, and the space between filled with sawdust—provide a double lid, and a hole at the bottom for the escape of the drip from the melting ice.

**Hellebore, Wet and Dry.**—"J. M.," of Tompkins Co., N. Y., writes: that our notice on "Mixing White Hellebore with Water has nearly cost me the loss of my bushes. It has done me no good at all. I always rely on your advertisements, but this time have been sold."—When one is unfortunate the desire to blame some one is quite natural. "J. M." does not say so, but he probably had used dry Hellebore successfully, he saw our direction for the easier and more economical method of using it in the wet way, tried it, and failed. The use of water seemed to be the cause of the failure, and as we advised water, we are, in the view of "J. M.," the direct cause of his trouble. We are not disposed to blame "J. M.," as he judged from what he saw or knew. There are two sides to all such cases: this is our side. When an application or process is advised in these columns, without qualification or comment, it is an indication that it has been found, either in our own experience, or in that of friends on whom we can rely, a proper or useful one. Whenever a thing seems probably useful, but has not been tested by ourselves or others, whose verdict we can adopt, we are always careful to state the source of our information, so that our readers can judge how far to accept it. Now take the present case. When White Hellebore was first used to kill the Currant Worm, it was always applied as a dry powder. So far as we are aware, our correspondent "Connecticut" was the first to apply it mixed with water. We tried it ourselves, and found it in every way so much better than the dry powder, that we have, each year, at the proper season, advised the use of water. As the advice which "J. M." says "nearly cost me the loss of my bushes," was based upon a yearly experience of over ten years, and the fact that the powder is also used in the wet state by the largest currant grovers in the country, it is just possible that the failure of "J. M." may be due to other causes. It is not easy to see why the powder, if active when dry, should

be any less so when wet, and it is much more likely that it had become deteriorated by long and improper keeping.

(Basket Items continued on page 325.)

## Bee Notes for August.

BY L. C. ROOT.

As I anticipated, Basswood commenced blooming much earlier than usual. I first noticed bees at work on the flowers June 25th. At this date, July 5th, the bees are working very freely upon them. If the weather is favorable, we shall undoubtedly secure a good yield, as the tree is blooming more freely than usual. Those who have followed our directions, and have had boxes or surplus combs properly arranged, will be amply repaid.

Three of our best Italian colonies have been selected, from which we intend to extract, and I shall report the amount of honey we take from each during the season. They are in the large "New Quinby Hive," and are furnished with 32 frames of comb each, from which the honey is to be thrown with the Honey Extractor. June 25th, we took from No. 1, 29 lbs.; No. 2, 32 lbs.; No. 3, 34 lbs.; July 5th, No. 1, 26½ lbs.; No. 2, 31 lbs.; No. 3, 35½ lbs. I propose to continue an accurate report of the products of these three hives, to show the readers of "Notes" that it pays to give bees care, and at the same time to illustrate the advantage of thoroughly comprehending whatever we undertake.

During the present month, take care not to add too many boxes, or to extract too freely, in localities where fall forage is scarce. I would advise every bee-keeper to leave a few hives without extracting all of the combs. In fact, where hoxing is practical, it is well to arrange a few hives with extra combs to be filled and capped over. I have frequently known seasons in which the brood combs were so entirely filled with brood that all the honey was stored in boxes. Then the yield of honey closing abruptly, but little or no honey was stored for winter. At such times, it is most desirable to have heavy cards of sealed honey that may be furnished to such stocks. In a word, we should not be so eager to secure a great surplus as to run the risk of starving our bees, which is sure to be the result of improper management.

The following inquiry suggests thought enough for several articles for the beginner: "What is the cause of bees buzzing about their hives on pleasant days, as if they were going to swarm? Mine have been doing this since May 1st, and have not swarmed yet. About the middle of the day a number of them rush out of the hives and fly in circles with their heads towards the entrance, and finally enter without going off any great distance." . . . *Answer.*—The occurrences similar to those spoken of by our correspondent will be noticed in every good stock of bees during the period mentioned. During each fair day the young bees leave the hive for their first flight. Our correspondent has described their appearance and actions at such times very accurately, but has made a mistake in supposing such to be any indication of swarming, only so far as frequent flights of this kind show that the stock is increasing in strength. The inexperienced are often led to suppose that bees are robbing at such times of busy flight. Our friend is evidently troubled because his bees do not swarm. Many bee-keepers watch the clusters of bees lying idle on the outside of their hives, and wonder that they get no swarms. To such, we would say, read up upon this subject, and see if there is not a much better way than to wait for swarms. If increase in numbers is desirable, practice has proved that it is much better to rear our queens in advance, use artificial comb-foundation, make a half dozen better and far more desirable swarms early in the season, and not wait for from one to three natural swarms, if so fortunate as to get any at all. In bee-keeping, as in all other pursuits, it pays well to investigate and keep informed as to the best methods of the day.

## The "Rose Bug."

The present year is remarkable for the abundance of insects, and not the least among them, is the "Rose Bug," or more accurately, the Rose Beetle (*Macrodactylus subspinosus*), has been sent to us by several who found it destructive to a variety of plants. The insect in question is not a large one, the body being about one-third of an inch in length, and covered with an ashy down. The slender legs are of a pale red color, and the joints unusually long. Though called the Rose Beetle, it is fond of many other plants, especially those of the rose family, as the apple, plum, and cherry—in some cases, the foliage of the latter has been badly injured, and they have caused much annoyance to those who have had cherries to pick. It is by no means confined to plants of the Rose Family, as it is often one of the grape-grower's worst enemies. It is very fond of the flowers of the grape, and often destroys great quantities of clusters. The female enters the ground to deposit her eggs, which are hatched in about three weeks; the young grubs

feeding upon the tender roots of plants. In late autumn, the grubs burrow deep to avoid frost, and spend the winter in an inactive state. As spring opens, they come up near the surface, change into the pupa state, from which they come out as the perfect beetle in the month of June. The beetle is active for about a month, when new eggs are laid, and the same cycle is repeated. The only time that a remedy can be applied, is during the mature state, when the beetle is above ground, and this consists in collecting and killing them by hand. In early morning, while they are sluggish, they may be brushed into a pan, in large numbers. In removing them from trees, a large sheet should be spread to catch them, as they are jarred from the tree. No poison has been used with success.

## A Talk about Medicines which it will be Well for All to Read and Think About.

QUACK MEDICINES—PROPRIETARY MEDICINES—"SPECIFICS"—MEDICAL ADVERTISEMENTS.

The statisticians say that at least 50,000 Deaths are caused every year by intemperance in the use of spirituous liquors, to say nothing of the incident poverty and suffering of the victims themselves—of their wives, children, friends, and the community at large, and of the crimes resulting; or of the absolute annual waste of many hundred millions of hard-earned Dollars. None of this will we controvert; but we may surprise some readers by asserting the belief—*First*, that if alcoholic beverages slay 50,000 annually, the so-called patent, proprietary and specific medicines shorten the lives of quite as many people, cause an immense amount of ill health, and involve the worse than waste of hundreds of millions of dollars every year; and *Second*, that a great deal of the intemperance in drinking is brought about by medical quackery.—The reasons for the above statements will appear further on.

### "SPECIFIC MEDICINES."

There is a wide spread, almost universal, popular belief that medicines are "specific," that is, that there is or may be found a particular medicine or medicines which will cure particular diseases; that one medicine, for example, will cure catarrh; that another will cure liver complaint; that another will cure consumption, and so on. The patent medicine makers act upon this popular error. They catalogue a larger or smaller list of diseases, give a great variety of symptoms—a list so comprehensive that almost any person, especially one with his nervous system, his stomach or his imagination slightly out of order, will find something that exactly hits his or her case, and then comes the positive announcement that such or such a medicine is a sure specific cure.

In the great medical libel suit against the *American Agriculturist*, terminating in its triumphant vindication Feb. 21, 1873, after running in the Courts for four years, several of the highest and best medical authorities were questioned in Court as to the number of medicines there were in the whole range of the *materia medica*, which could be called "specifics." None of these authorities were willing to name a positive specific, with a single exception. Dr. M. R. Vedder testified that he believed "sulphur, properly applied, would always cure the Itch, and may therefore be called a specific." Even to this it might be objected that the "itch" can hardly be called a disease, as it is the result of the biting of minute vermin, not unlike human lice, lice upon poultry and other animals and upon plants, the scab on sheep, etc. In the itch the vermin are too small to be seen with the eye unaided by the microscope. The cure depends upon poisoning or smothering the animals, which is effectually done by the application of lard mixed with sulphur, or with mercurial salts, etc.—the sulphur being preferable despite its disagreeableness, because it has no injurious or poisonous effect upon the individual.—Some of the Physicians stated that quinine was nearly a specific for malaria, yet with the reserve that some persons were injuriously affected otherwise by quinine, that it sometimes failed in particular cases, and that ordinary persons not skilled in medical science and diagnosis, could not be certain that their sickness was caused by malaria; and further, that the most skillful medical men could not always decide this point unqualifiedly. And just here is one great objection to all kinds and classes of medical nostrums, patent medicines, proprietary medicines, or good medicines sold to the general public and taken without the direction of skillful, educated, experienced medical observers. It is literally true that "what is one man's meat is another's poison"—that what will aid in the cure of a particular disease in one person will be injurious to another person affected by the same disease, but in different circumstances as to constitution, physical condition, etc.

### EVEN PHYSICIANS SEEK ADVICE.

It is well known that the most skillful physicians when seriously sick themselves, or when any one in their fami-

lies is very sick, never prescribes for himself or those dear to him, but calls in another physician, even if he has to summon one whom he knows to be quite inferior to himself in medical knowledge. His experience has taught him that any person with a system sufficiently disordered to need the aid of medicine, is *not in a condition* of mind and judgment to decide as to the kind of malady, or the proper remedies in his particular case. And yet many millions of people with no proper understanding of the human system, are constantly dosing themselves with the advertised and he-puffed medical nostrums that load down the shelves of all sorts of establishments and sales shops, and now, indeed, of nine out of ten of the regular drug stores of the whole land—and the advertisements of which fill the columns and furnish the support of the great mass of newspapers throughout this country and some others.

### CURING BY IMAGINATION.

It has been said that "the best physicians give medicines in many cases to amuse the patient while nature is working out the cure." That such is sometimes the case we have no doubt; indeed, we know an excellent physician who was for twenty years called from once a month to once a week to see a lady in good circumstances and of more than ordinary intelligence, though at the same time of a nervous temperament. The lady always asked for a "prescription," but the physician preferred, in her case, to prepare the medicine himself, which he sent to her in the form of small pills. These pills were merely cracker crumbs made up with gum arabic and rolled in powdered rhubarb or whatever would give them the odor of "the shop." As simple and inert as they were, the pills invariably cured.—The one redeeming feature in this whole patent medicine business is the fact that *some*—would that we could say *all*—of the so-called remedies are actually as inert as the above mentioned pills—producing no other effect than to amuse those who are actually ill, while nature is curing them, and have a soothing influence on those whose disorders are of the imagination only.

### MEDICINES PRODUCING INTEMPERANCE.

But there is a darker side to the picture; many, indeed most, of the medicines are not thus harmless. Most of the liquid medicines consist largely of whiskey or other cheap form of alcohol, qualified with some stuff to give a medicinal taste. Even the so-called "Temperance Bitters," and others claimed to be non-alcoholic, are open to this charge. We once collected twelve varieties of these compounds, all said to be practically non-alcoholic, and on subjecting them to simple distillation, no one of them failed to yield less than nine per cent of pure alcohol, and one labelled "Temperance," gave 28½ per cent of alcohol: common whiskey contains only 40 to 60 per cent of pure alcohol. If one takes a dose of a medicine of this kind, the alcohol acts as a temporary stimulant, and if the stuff contain Gentian or a similar drug that has a transient tonic effect, the patient "feels better" at once, even though he may not be, and usually is not, really ill. He at once is convinced; "That's the medicine," is his implicit belief, and he not only continues to take it, but commends it to friends and neighbors, who go through a similar experience of "feeling better," and the medicine has a "run"; certifies as to its excellence are given, and the stuff has a large sale.

But what is the result? Those who take it once, repeat the dose on every occasion of real or imaginary change of feelings from the slightest cause. Over-work, over-eating of poorly digestible food, loss of sleep, business troubles, or whatever causes one to feel "out of sorts," induces a resort to the "Bitters"—or whatever the stuff may be called. What should be, and what would be good health, but for the dosing, is destroyed. In fact, the person is, unconsciously no doubt, actually indulging in a moderate "spree." Indeed, a taste for alcoholic stimulants is thus formed, which often in the end leads to intemperance. When through this dosing the system becomes habituated to its use, and enlarged doses cease to have their former effect, the patient looks over the long medical advertisements, and finds some "symptoms" there described which seem to hit his or her present case, and a new medicine is tried. This new stuff may be either more strongly alcoholic or more positively tonic than the other, and for a while appears to be the needed remedy; but the system soon becomes habituated to this, and possibly another and another of these nostrums is tried, until the end is confirmed illness, and thus the grave is often reached long before it need have been. The same general effects follow.

### PROMISCUOUS DOSING

with any other form of medicine. The popular pills, for example, are of two kinds. They may be nearly or quite inert, and serve to amuse the one who takes them while nature and rest work a cure, or they are the simplest possible cathartic, and act upon the fact that in the beginning of many forms of illness a smart movement of the bowels is just the one thing needed. The harm done by these is, that special virtues are ascribed to, and a high

price is paid for, a nostrum which accomplishes no more than would a dose of some simple remedy like Calcined Magnesia or Powdered Rhubarb. One feels better after a dose of this or that pill, and advises his friends to use them; the maker sells for 25c. what costs him but a cent or two, and fortunes are made from a pill of which, were there a general knowledge of the simplest laws of health, not one could be sold.

These illustrations apply to about all varieties of "patent" medicines, so-called—though they are not patented at all, but are really secret remedies. We have looked into this subject, and our observations during these many years have fully satisfied us that these "patent" or quack medicines have, in our country at least, killed more persons and caused more suffering and more want than all the wars since the Declaration of Independence, and that in the annual destruction of life and health, the use of these medicines and the intemperate use of alcoholic drinks are twin agents of the King of Terrors. A physician lately said to us: "If the sale of medicines were entirely stopped, except when prescribed by a regularly qualified physician, it would compel half the doctors in the country to go into some other pursuit or starve, for the use of quack medicines supplies more than half the business to the medical profession."—And the remark is undoubtedly true.

#### QUACK MEDICINE PROFITS.

Immense fortunes have been, and are still being made by a few from the manufacture and sale of these secret compounds. There are many miserable failures also, but these are seldom heard of. One great element in the success of these things is cheapness; the first cost of the article must be very low. The most important point is to hit upon a taking name, and one that will convey the idea of applicability to a wide range of diseases—there is "much in a name," in this case. There must then be an account of the origin of the stuff—its discovery, and this should be such as to throw about it an air of mystery, or the glamour of romance or fable. The cost of the stuff being low, the retail price should be correspondingly high—a price of \$1, \$1.50 to \$3 for a bottle or box that costs 5, 10 or 15 cents, allows, after giving the retail agents a liberal discount of one-third to one-half, something to pay for wholesale advertising and still have a "living profit" left for the maker. It requires some capital to launch such a thing, and get it started. There must be a general outbreak of advertising, a giving away of a few dozens on trial, and if the stuff only has whiskey enough in it to make people "feel better," certificates to its excellence can be obtained at once, though those from patients who have been cured as well as from M. D.'s who testify to its efficacy are easily made up at the start. The advertising of these things is an art of itself. There are papers, we are sorry to say, that will sell whole columns—yes, whole broad pages, to the stirring announcement, and if these give a sufficient variety of symptoms and a strong list of wonderful cures, the thing may go. It will be wonderfully helped if almanacs advertising the stuff can be scattered by thousands, and circulars of convenient size to use as wrapping paper are furnished dealers in small wares free of cost.

#### PLENTY OF VICTIMS.

All experience shows that among some 40 or more millions of people there will be found, if the work is done effectively, some hundreds of thousands, if not millions, of nervous imaginative persons with supposed or real disorders who are always ready to try any new thing that claims to afford them relief, and it is these tryers who afford a large supply of regular customers—for a while at least—for every new medicine that is offered.

Such in brief is the real history of each one of the so-called "patent" medicines, that are now before the public, or have passed into the limbo of things forgotten. Let any one notice at the freight depots and see the hundreds of tons of these health-destroying, death-dealing "medicines," and then look at the columns of the majority of the ordinary newspapers and see how largely these sheets are sustained by the advertisements of a trade that keeps hundreds of printing presses and even paper mills at work, and he will have some idea of the magnitude of this traffic, and will not wonder that in some cases large fortunes result from it—fortunes to a few—but what of the many who support it at a fearful cost of money and health, and life?

We would not imply that all medicines that are put up and offered for sale are objectionable, for some, like a well known extract of ginger and a few others are not secret preparations; their composition is known and their effects well understood. But the great mass of the secret medicines offered to the public are health and life destroying, and those who assist in their distribution in any manner are, to say the least, in bad business. No journal assuming to be a director of public opinion, or a conservator of the public good, should be so ignorant as to have any part in this nefarious business.

We need hardly warn the reader to let every thing of the kind alone, and to not tamper with his health and vigor by taking anything, of which he does not know

the composition. In most slight ailments attend to the diet and nature will do the rest. If really ill enough to need medicine, do not be wiser in your own conceit than the skilled physician, who goes to another in sound health for advice, but like him remember that a disordered body affects also the mind, and when advice is really needed, seek it from a proper source. It will be an immense saving in money and in health—in life.

#### NEVER READ MEDICAL ADVERTISEMENTS

of any kind, in newspaper, almanac, or circular. They will only work upon your fears, by their skillfully array of symptoms and cures. Your imagination will most likely find some "symptom" which it will do no good to learn about. It is told of a certain nervous medical student that in going through his text-books he actually believed himself affected with nearly every disease of which he read a minute description.—A number of medical gentlemen once arranged themselves to meet at different points on the road a gentleman who was to come home from a village a dozen miles away. Each inquired after his health, and spoke of how ill he appeared. The man came to believe himself really sick, and on reaching home, went to bed, and had quite a course of fever.

#### FINALLY,

the readers of the *American Agriculturist* have not for a quarter of a century been troubled with any of these distressing medical advertisements in its columns. It has cost an effort, at times, to reject some of the better class of these—if there can be any better class among things absolutely bad—especially as by this course we cut off a large source of profitable income. Those who make a thousand per cent upon their stuff, can afford to and do pay large sums to reach the people with their array of "symptoms." But we believe our readers prefer paying more for "clean pages." When they are unwilling to do this we want to go out of the business of publishing. Neither our pages nor our backs can furnish bulletin-boards for announcing what we believe to be only a public detriment, or worse.

### Editorial Correspondence. — Items from "Notes by the Way."

[Mr. Orange Judd has resumed his customary summer tours of observation among farmers. These extended last year as far west as the Rocky Mountains, including Nebraska and Colorado on the south, Minnesota, Wisconsin, etc., on the north. A portion of last season's notes unaccountably disappeared from his travelling bag—those from Colorado, part of Nebraska, Mich., etc.]

#### Where Travellers Should Go.

Every year many thousands go on pleasure trips across the Atlantic, without having first seen our immense western country, our own majestic mountains, our grand rivers, such as the Mississippi, Missouri, Ohio, etc.—many not having even seen Niagara. It is not well to do thus. There are no rivers in Europe to be compared in size with our own. The Rhine has a little strip of 60 or 70 miles between Bingen and Coblenz, of much interest on account of the tumble-down old castles, and the legends connected with them, but nothing to be compared in scenery with the Upper Mississippi between Minneapolis and La Crosse, and even down to Clinton, while from Cairo down a thousand miles, it is simply grand from its width and great bends. A ride of 1,000 miles from New England or New York to Chicago; then of 500 miles from Chicago to Omaha, and another of 500 miles on to Cheyenne, over the broad plateau, greatly expands one's ideas and enlarges his conceptions of the vastness of our country. No journey in Europe approaches it, unless it be a trip from Berlin in Prussia to St. Petersburg in Russia, thence 700 miles from St. Petersburg southeast via Moscow to Nijni Novogorod on the Volga. A journey of 750 to 1,000 miles northwest from Chicago, across Wisconsin, Minnesota, and out into Dakota, is of almost equal interest—with its pleasure greatly heightened by a return via Duluth and down through the great lakes to Buffalo or Montreal.—A trip of 800 miles south from Cheyenne, down through Colorado's Plaius, to Colorado Springs, and the adjacent Pike's Peak, with side journeys into the Rocky Mountain mining regions, has, or ought to have, more of interest to every American than a run over Switzerland—at least the former should first be taken, and the trip is far less expensive, and has far less annoyances. A line addressed to the Union Pacific R. R. Company, at Omaha, Neb., will bring descriptions of the

route and particulars as to cheap excursion tickets. A similar line addressed to the Chicago & Northwestern Railroad Office in Chicago, will bring like information about excursions to the northwest.

#### A Noteworthy School.

The Seminary at Lima, 18 miles southeasterly from Rochester, N. Y., has done a grand work during the past Fifty Years. Of the Twenty Thousand or more Students, mostly over 14 years of age, who have enjoyed its educational advantages, a very large proportion have come from the farm homes of Western New York, though not a few have come from more distant localities, Canada supplying a liberal share. Many of these students, of both sexes, are now occupying high positions of honor and usefulness all over our own country, and some abroad; but the larger number of them have returned to the farm, and are now the intelligent Cultivators and House-keepers so numerous in the "Genesee Country." At the great "Semi-Centennial" Gathering, June 6-10, we met perhaps a hundred or more of those with whom we studied 37 to 40 years ago—almost all of them with fast silencing locks, but with the intelligent countenance that shadows forth an educated mind. How the hopes, the ambitions, the struggles of early manhood, come back afresh when one meets and recognizes so many earlier companions after the long separation. Who could fail to "renew his youth" on such an occasion? While many of our readers would enjoy an account of the Semi-Centennial exercises, we must not take space for this that belongs equally to hundreds of thousands of others not personally interested. We will, however, speak of

#### One Feature of the Seminary at Lima,

which specially characterized it during its earlier years, and is still kept up somewhat at least. We refer to the facilities for superior educational advantages at *low cost*, both for tuition, board and incidentals. While the Institution furnishes advantages equal to nine-tenths of the so-called Colleges, for everything from common English to the higher studies, the tuition charges are but nominal, and in our day at least, it detracted not one whit from a student's standing, or from the esteem of his teachers and of most of his fellows, that he wore home-spun, that he boarded himself on 25 cents, 50 cents, or a dollar a week, and *earned it* as he went along, in the garden, in the haying and harvest fields, in mechanical work, in peddling, in canvassing for books and periodicals, in repairing clocks during vacation, etc., etc. We know a good many who came to Lima from small farm homes 35 to 40 years ago, with only a few dollars in their pockets, and boarded themselves in small attic rooms rented for 25 to 50 cents a week, who literally earned their way, who stood high as close students, and who are now occupying most important and influential positions—some of them owners of grand, well-cultivated farms, some presidents of colleges, some judges and governors, some distinguished ministers, some editors of leading journals, etc., etc. The early habits of *economy, of self-reliance, of push*, acquired in such circumstances, are of invaluable benefit, in all after life, whatever one's occupation, calling, or position. Multitudes of farmers' sons and daughters from 3 to 30 miles or more around, hired their little rooms, furnished them from home, and received their provisions from the home stores once or twice a week. Probably during 50 years past five to eight thousand or more farmers' sons and daughters have received more or less of superior education that they would not and could not have obtained but for such economical facilities as were supplied, and the system of living, in one sense, fashionable at Lima. The high and graded public schools, now so common, have been in existence but a few years.

#### Windmills Good on Eastern Farms.

The windmill is found so useful throughout the prairie regions that one can hardly drop down at any spot between Indiana and the western limits of settlement, without seeing one to a dozen farm windmills within range of the vision. Until quite

recently they have not been considered specially adapted to eastern farms, except when there chanced to be an unusual wind exposure.—In our present journey up through New York State, we find a considerable number in operation, and learn that many more are ordered, or to be ordered, for this season. We write this  $1\frac{1}{2}$  mile east of Lima, Livingston Co., sitting under the covered frame of a "Stover" Windmill on the farm of Samuel Bonner. This mill has been in use over a year, and, with the exception of a single day, has, summer and winter, supplied some 40 head of cattle and horses, and 50 or more sheep, with fresh water from a deep well, and not a tithe of its power has been required. No care has been needed except to stop it when not wanted, and no expense except a little oil for its gearing, while it promises to be good for a dozen or twenty years. It is on a level farm, stands on a frame 40 ft. high; wheel 10 feet diameter. It is entirely self-regulating, the wings turning edgewise to the wind when it blows too strong, and any desired rapidity of motion can be secured, whether the wind be high or only a light breeze. The cost was \$100 for the mill and gearing, and the agent supplied and put up the frame, all complete, for \$25 more.

Mr. Bonner afterwards boarded up the lower part of the frame, making a comfortable room for tools, etc., at small additional expense. The pump is a double-gear force-pump, so arranged that the whole or part of the water can be driven out of the top spout to the water-trough, or a part or the whole be driven into a side-pipe below the surface, which carries it to any desired distance. Some send all the water thus to a milk-room, where it surrounds milk cans, and flows from thence back to the stock yards. Others have a branch pipe into the dwelling for the house supply of water. The windmill will force it to any desired height, as to a tank in the house chambers or bath-room. This pump, with tubing, costs about \$25. Cost of the whole \$150.—Allow ten per cent per annum for interest and wear, and the annual cost is only \$15, which is saved several times over in the labor of pumping water for the stock alone. There is a supplemental hand-lever that can be readily used for hand-pumping if needed, but there has been only a single occasion to use this in a year, in a dry time when there had been no wind stirring for several days.—[On the farm of A. W. Comstock, two miles west of Lockport, N. Y., we saw an arrangement like the above, except that the shaft from the windmill was attached to the top of the rod of a common wooden pump, reducing the total cost to \$125, as the pump was already in the well. The windmill frame is 34 feet high. It supplies abundant water for 50 cattle and horses, and for dairy purposes. Mr. Comstock keeps some 40 cows, and by special care and skill secures a cheese that sells to regular customers at considerable above the market rate. He uses no ice, but cools the milk in cans in a large box near the windmill which keeps a supply of cool water around the cans.]

#### Protected Water-Trough for Stock.

Near the windmill, on Mr. Bonner's farm, we saw a convenient watering trough or tank, which may be useful in most cold regions. A supply of water, not usually ice cold even in winter, is desirable for all domestic animals. The tanks may be of any desired size. Mr. Bonner's consists of an inner water-holding plank box, A, 11 feet long, 4 feet wide, 22 inches deep, holding about 18 barrels, and open at the top. On the four sides a box, B, is built of inch boards, 12½ feet long, 5½ feet wide, and 30 inches high, which leaves a space of 8 inches all round for filling with sawdust. A double cover is made of boards 8 inches apart, with an opening at the side next the stock yards, 7, 8, or 9 feet long, and some 2 feet wide. The sides of this are boarded up, the opening being a little smaller at the bottom. All the enclosed space is filled with sawdust,

the same as the sides. A double cover, C, to fit the opening is made and also filled with sawdust. This cover has heavy strap hinges at the back, and is nearly balanced by a stone, or other weight, W, attached to a cord, P, running over a post to the rear of the tank, so that a child can lift or close the tank cover. At Mr. Bonner's the cord runs to the enclosed room around the base of the windmill frame, and an iron weight is attached there, so that the tank cover can be opened and closed from this room. The front of the tank is sufficiently banked up for sheep to reach the water. An inlet pipe comes from the pump, and an overflow pipe from near the top of the water box carries off surplus water. The whole arrangement is easily and

PROTECTED WATER TROUGH FOR STOCK.

cheaply constructed. The water from the well is not very cold, and being frequently changed by fresh supplies, seldom freezes. During last winter ice was seen in the tank but once, and then only a thin film, which dissolved in fresh water.

#### Value of One Improved Animal.

In Mr. Bonner's barn we noticed a good Shorthorn Bull, two years old last spring, thorough-bred, registered, that cost \$150 we believe. He was kept for the double purpose of improving the stock of the farm and of the neighborhood as well, and for the latter purpose was let at the low rate of \$2 per service. His progeny for the present year will number at least 60, yielding say \$120, though a considerable number of these will be in the home herd. A little figuring will show the value of a single such animal. The calves will be worth \$8 to \$10 each at one day old, while the ordinary "natives" sell for only \$1 each when dropped—an increase of \$7 to \$9 each. Call the increased value only \$5 each, a very low estimate, and the increased value of the 60 calves will be \$300, or twice the cost of the bull. But look ahead a little: The expense of raising 60 animals to three years old will be about the same for natives or good grades; but at that age the improved animals will sell for at least \$25 more per head—equivalent for the 60 animals of this one year's get, to at least \$1,500. Let it be kept in mind that this result will surely come from keeping this one \$150-animal a single season, while his value a year hence will be quite as large as now. And this result may be depended upon annually for half a dozen years. There is no doubt that the above figures will be fully realized. Query: Why are not more such breeding animals introduced into every neighborhood where farm stock is kept?—Similar figures apply to horses, swine, sheep, etc.—A multitude—indeed the great mass—of farmers do not hesitate to graft their native apple trees with improved cions, yet they are satisfied to keep on raising, caring for, and using "scrub" animals, when every dollar expended in improved blood is speedily returned many fold!

#### The "Genesee Wheat Country."

Forty to forty-five years ago, when we were personally familiar with the farming in this region, Winter Wheat was the chief money crop. The counties of Genesee, Livingston, Ontario, Wayne, Monroe, Orleans, Niagara, Cayuga, Onondaga, Seneca, Cortland, and at least a part of Erie, Wyoming, and Yates, embraced what was once known as the "Genesee Wheat Country"—a district producing such excellent grain for flouring, and in so large amounts, that it was known the world over as the wheat field of America. About

40 years ago, we believe it was, the insects began their extensive ravages. But after they became less troublesome, wheat remained in disfavor; farmers said the soil was "wheat sick," and for a long time wheat was almost a secondary crop. Ohio, Indiana, part of Michigan, Wisconsin, Minnesota, and the far Northwest, successively led in the reputation for winter wheat, while Illinois, Iowa, Kansas, and Nebraska, one after the other, came forward with the immense supplies of excellent spring wheat. But judging from what we have seen during a few years past, and especially during the present journey, the "Genesee Country" is fast regaining its former position as a great wheat producer, and Ohio promises this year again to come to the front. During a few days past we have seen in Livingston, Genesee, Niagara, Monroe, and Orleans counties a great number of fields of standing wheat—in close succession all along the routes we travelled—that fairly eclipse anything we remember in the olden times—fields whose thickly standing, uniformly distributed, strong stalks are crowned with heads that indicate 25, 30, 35, and often 40 bushels per acre.

#### Whence this Improvement?

We talked with many farmers, and the answer seems to be: (1st.) Rest of the soil, that is, time given for sun, air, moisture, and frost, to release fertilizing elements previously locked in undecomposed rocky, or stony fragments.—(2nd.) Improved varieties of wheat, among which the "Clawson" seems to be the leading and favorite variety.—(3rd.) Better mechanical working of the soil by improved implements.—(4th.) A judicious rotation of crops.—(5th.) Much freer use of fertilizers, especially, (6th.) The use of superphosphate. Of the last named, we have seen remarkable instances. For example, we have gone through wheat fields that promise 25 to 35 bushels per acre generally, while strips through the same fields will hardly yield 10 bushels per acre. The soil and treatment were the same every way, except that the poor strips did not receive the 200 to 300 lbs. of superphosphate per acre, which was applied to the rest of the land. These are exceptional cases, but other fields point in the same direction.

#### A Crop Rotation.

The system of rotation of crops in the wheat-growing section of Livingston County, N. Y., and we believe it is substantially the same through the "Genesee Country," is about as follows:

- I.—Wheat with some Timothy seed sown in October, and liberal Clover seeding in spring.
- II.—Pastured somewhat in autumn.
- III.—Clover mown, with second crop ("rowen") cut for seed.—Variation, pasturing instead of mowing, if needed for that purpose.
- IV.—Early clover growth turned under and corn planted, the chief yard manure of the rotation being applied to the corn.—Variation: If the clover is doing well and hay or pasturage is specially wanted, the clover is allowed to stand over another year.
- V.—Barley (or oats) in spring on the corn stubble, with wheat in autumn, with phosphates. Some apply part of the yard manure of the course, as a top-dressing to the wheat in autumn, while others plow it under in preparing the wheat land, especially if the manure is not well rotted.

#### Manuring with Brains.

In our travels we visited the farm of one of the old readers of the *American Agriculturist*, who exemplifies our Timothy Bunker, Esq.'s brain-manure theory. (We shall not give name or location, for our subscriber is entitled to continue his practice until his neighbors become wise enough by reading this or some other journal, to utilize their home supplies). Every spring our subscriber sends out a man with a large box-wagon into all the region round about, to clean up their hen-roosts for them. He finds them quite ready to let him gather all the droppings he can scrape up and take away, at 15 cents per bushel. He generally collects 30 to 40 bushels a day, according to "the

finds" he chances upon, as the gold miners would say—though he understands the region so well that he knows where the best "lodes" are to be found. This manure is brought to the covered manure deposit, where it is mixed with dry earth, and some plaster and salt, to about double its bulk. Applied at the rate of say 10 bushels of the mixture per acre, to corn, and indeed to all other crops, it produces grand results, at less than one-fourth the cost of Guano or the best Superphosphate, and even at far less cost than the best and cheapest barnyard manure. Brains do pay in farming!

#### Farms of Charles Keep.

A variety of items were noted during a visit to the farms of Charles Keep, about two miles east of Lockport, Niagara Co., N. Y. Mr. Keep has been in business many years, and recently turned his attention largely to agriculture. He has some 500 acres in adjoining farms, which are "worked on shares" by two or three experienced men, but the owner, we judge, takes a lively interest in the direction and management, as he seemed to thoroughly understand every item, and but from his own account, we should have supposed he is himself the farmer. First we noticed the windmill, which has been doing effective service for three years, and very satisfactorily too, in supplying all the water for a large amount of live stock, and other purposes. The wings somewhat resemble an old-fashioned bonnet, with the lower or back half of the crown cut off. It is named the "Nysewender's Turbine Windmill," made in Ohio, by Mast, Foos & Co., all the parts being of iron. The cost, the self-regulating, etc., are similar to other good forms of windmills. Mr. Keep prefers the iron wings, because less liable to the action of the sun and moisture. [There are at least seven or eight good self-regulating windmills, any one of which will do excellent service, such as the "Halladay Mill," made by the U. S. Wind Engine and Pump Co., Batavia, Ill.]

#### Cement-floored Horse-stalls.

The floor of the horse-stalls, stalls, and carriage room, is made of a thick layer of small stones, gravel, and sand (at the top), all bound into a solid stone-like bed, with hydraulic lime. Under the stalls it inclines sufficiently to carry the urine to a broad but shallow gutter, and this falls enough to take the urine and washing-water off at one side. The vehicles stand upon the same kind of flooring, a little higher than the stalls. Under the horses, for them to stand upon, 2-inch-thick plank are laid half an inch apart; the openings serve as gutters to carry the urine over the cement below to the rear gutter. As this cement extends to the walls all around, there are no hiding places for rats.

#### Fattening Lambs for Spring Mutton.

In December of 1879, Mr. Keep, with his lessees, bought some 900 lambs from the farmers in the country around, at an average cost of about \$2.50 each. About 400 of these were kept in the high basement of a large barn, surrounded with heavy stone walls, with windows to admit moderate light and for ventilation as needed. This basement was all in one room in the form of an L, the two longer sides being 130 feet each, one arm 30 feet wide, and the other 40 feet wide, furnishing 7,900 square feet of floor room. There are six ventilators from each sheep-room, 15 to 18 inches square, running up through the barn, to carry off foul air, surplus heat, etc. The flooring is of cement, the same as the horse stables, with suitable depressions for carrying off water if needed. About 500 of the lambs, with some sheep, were kept in the basement of another barn on an adjacent farm,—a single room 160 feet long and 56 feet wide, giving about 9,000 square feet of flooring—cemented like the other. The lambs were separated into lots of 15 to 25 in pens, formed by movable feeding racks (described and illustrated below.) Water troughs, supplied through pipes from the windmill pump, were placed at convenient points.

#### Portable Sheep-Racks and Pens Combined.

Those in Mr. Keep's Sheep-room (the barn basement room) are constructed thus: Corner posts, *a, a,*

of 3½x2 inch strips, 3½ feet high. A 6-inch board, *b, b,* all around the top. About 20 inches from the ground a 6-inch board, *c,* is nailed on in front and at

Fig. 1.—PORTABLE SHEEP-RACK COMPLETE.

the ends, and an 8-inch board, *d,* along the back. A board 6 inches wide, *e,* is fastened underneath along the front. Back of this a 16-inch wide board, *f,* stands inclined against the back. This slides the corn or roots down into the trough formed by the front and end boards, the narrow bottom piece, and the inclined board.—In front, perpendicular strips, *s, s,* about 4 inches wide, are nailed on, leaving the openings between them about 7 inches wide—but further apart if for large and full-grown sheep.—These racks are about 18 inches from front to rear and generally 16 feet long, but vary in length to suit the divisions required. In use they are arranged to form sheep-pens oblong or square—the walls of the room forming one side of the outside rows of pens. The general form is a 16-foot rack set parallel with the walls, and two others 12 to 15 feet long forming the other two sides, or one of them shorter to leave a passage to a water trough. The backs of the racks of two sets of pens are set 3 to 4 feet apart, leaving a passage way for carrying in the feed—hay, roots, and corn. The manure is taken out two or three times during winter, when the ground is frozen, so that it can be taken on to the fields. When not in use these portable racks are piled up at one end, leaving the room free for driving in teams to haul out the manure. Two men can handle them readily. To reach the sheep, or let them out or in, the ends of the racks can be swung round like a gate. They are made by contract at a neighboring shop, at the cost of 15 to 16 cents per running foot.

Fig. 2.—SHEEP-RACK.  
(Enlarged End View.)

#### The Lambs were Sheared in December.

The warm room, with the heat of the flock, kept them from being cold, and they maintained a healthy condition. Abundant straw was daily supplied, to thoroughly absorb all liquid and solid droppings, and furnish dry warm bedding. As it accumulated, the feeding racks were raised to stand upon it. It was believed that the lambs would grow and fatten faster, with the wool thus removed, while the wool-clip sold for nearly enough to pay the purchase cost of the animals—owing to the extraordinary advance in price last winter. (The farm account-book shows the sales from 500 lambs of 2,733 lbs. of wool, unwashed, for \$1,071, or about 39 cents per lb.) These lambs were mainly grade Merinos, estimated to average about 50 lbs. each, when bought.

#### Feeding and Profits.

The lambs were supplied all the clover hay they would eat, and they nibbled somewhat upon the fresh straw as it was daily supplied for bedding. They also had corn in the kernel (unground) beginning with one bushel per day for each 100 lambs, and gradually increasing until they finally had all they would eat. They also had daily rations of turnips (mangels); the 900 lambs and 200 sheep consumed 8,000 bushels—say 7½ bushel each—during the winter. After three months feeding, they had increased to an average of 97 lbs. each (varying from 80 to 130 lbs.); they were in high condition,

and were taken by dealers, in two large lots, mainly for the New York market, at five and five-eighths (5½) cents per lb., live weight, or over \$5 per head. The price received for the wool, with the final sale, left just \$5 per head for three months feeding and care. No account was kept of the cost of the feed or of the value of the manure; the feed being all grown upon the farm, the profits went into the general profits of the farm for the year. (In another conversation we learned that the sales from 130 acres, divided between the Owner and Lessee, after deducting the cost of 500 lambs, amounted to \$4,400, or \$33.84 per acre—\$16.92 per acre going to the owner for the use of the land, with the soil in an improved condition, and the large supply of sheep manure to enrich it still further for future crops. Mr. Keep gives large credit to the Lessee, Seneca B. Foot, for the successful results obtained.)

#### Soiling Stock—Hiring Sheep Pasture.

Mr. Keep believes it more profitable to have all his arable land constantly growing crops. Clover seed (with no Timothy) is sown freely every spring upon the wheat fields, with 100 to 150 lbs. of plaster per acre, sown broadcast. The meadows are usually mown twice a season, and the cattle are kept in yards, but allowed the range of the wood lots in hot weather. He supplements any deficiency of clover to furnish a full supply of hay, by using Hungarian grass, sowing 3 pecks of seed broadcast, on well manured land, and cutting and curing the crop just like other hay. The stock sheep are hired out to pasture on neighboring farms at 2½ to 3 cents per week each, during summer, where they have a partial range of woods, and they are fed during winter on clover and mangels, with corn if to be fattened off for spring mutton.—All the wheat and other straw is housed in the large barns, and used freely enough to absorb the entire solid and liquid manures from all farm animals. Both cattle and sheep pick it over and eat more or less of it with their richer clover and Hungarian grass. The amount of good manure thus secured from the live stock keeps the fields up to a high state of fertility.

#### Phosphates Producing no Effects.

While some farmers in the vicinity have found Superphosphates of much benefit, this has not been Mr. Keep's experience. He asked us to go through a wheat field which had received 200 lbs. per acre of Lister's Superphosphate, and pick out the strips left without Phosphates for comparison. We were utterly unable to select them or to find any difference in the growth of straw, or size and plumpness of the heads, though we passed back and forth across the strips with and without phosphates. Before giving it up, Mr. K. will try another brand of phosphates, to see if the lack of effect upon the grain crop be not due to poor quality.

#### Wheat after Wheat.

The field of 22 acres above referred to is mostly a heavy clay, drained only by ridging and deep dead-furrows. In 1878, it was an oat stubble, with little vegetation upon it. After summer-fallowing it was sown to wheat; the dead-furrows were too shallow, and it drowned out so as to yield only 10 bushels per acre, and the clover did not catch. After cutting the wheat, 250 sheep were turned in, and they ate up about every green thing, including a considerable supply of Canada thistles, of which they even ate the plowed up roots, so that none are visible this year. As it was plowed, the soil turned up in large clay lumps. These crumbled in the sun and rain by the last of August, when the harrows and clod-crushers were kept on until the surface was fine. Five heavy loads per acre of well-rotted manure were harrowed in, and the first week in September wheat was drilled in with 200 lbs. per acre of phosphate above noted, except on the test plots. The dead-furrows were cut deeply and clover sown last spring, which shows a good catch.—To-day (June 15) the whole field shows good for 25 to 35 bushels per acre, the latter on the driest portions. It goes against the opinion of those who predicted a failure in wheat after wheat. But this is a strong clay soil, and it was finely manured, besides the previous crop was poor.

# A Half-Stone House, Costing \$2,000.

BY S. B. REED, ARCHITECT.

The design here given represents a substantial and convenient house for well-to-do farmers, or others, who may find it suited to their circumstances. The outside walls of the first story are of stone, and for this reason the design will be of special interest to those living where building stone is at

Fig. 1.—FRONT ELEVATION OF THE HOUSE.

hand. In point of economy, where stone walls are determined upon, there is an obvious advantage in this half-stone method. The ratio of cost in all masonry increases in proportion to the difficulty in elevating and handling such heavy materials above a convenient height.... **Elevation** (fig. 1).—The outside and openings are symmetrically arranged. The walls of rough masonry accord entirely with the sense of fitness for all rural structures, and they may be made very pleasing in appearance by distributing close clinging vines along their sides, which soon grow, and add greatly to the home-like aspect. The foundation or cellar walls show 18

Fig. 2.—PLAN OF THE CELLAR.

inches above the ground, just sufficient to allow for windows to supply necessary light and ventilation to the cellar. The principal walls being of stone, there is very little outside wood-work to be

destroyed by dampness from the ground or shrubbery. The body of the building may therefore be set as low down as desirable for convenience. The site, however, should be elevated, for dryness and appearance. The earth taken from the cellar excavations will be sufficient in most cases to raise the grounds one foot immediately surrounding the house.... **Cellar** (fig. 2).—The height is 6½ feet. It has suitable windows for light and ventilation,

and at the same time is sufficiently below ground to be warm in winter and cool in summer. An outside entrance is placed under one end of the rear veranda. The Chimneys are centrally located, and have openings in them for ventilators leading through continuous flues to the top. Stairs are arranged leading to the kitchen above.

.....**First Story** (fig. 3).—Height of ceiling, 10 feet. A hall, three rooms, pantry, rear entry, and closet form the general divisions of this story. There are three outside entrances, one in front and two in the rear. The Main Hall is of convenient shape and size, and is entered from the front porch; it connects with each of the principal rooms, and contains the main stairs. The Parlor is octagonal in form, with open-

ings symmetrically arranged, and with windows disposed to the best advantage for outlooks and views. The two sides are unbroken, giving space for wall furniture. The Dining-room is of fair dimensions, and is accessible from the outside through the front hall and rear entry; it is in convenient connection with the parlor and pantry, and has windows in front and on one side. The Kitchen is conveniently arranged, has an open fire-place suitable for a range, with a large double window opposite; it connects through doors with the main hall, pantry, cellar stairs, and rear veranda, and contains a pump, sink, and three wash-tubs. The Pantry is full size, has an outside window, and is thoroughly shelved. The rear entry is designed as a private entrance, and has cleats and hooks for overcoats, etc. The chimneys are located where the warmth will be saved to the interior, and greatly lessen the quantity of fuel required to keep the house warm in cold weather.... **Second Story** (fig. 4).—Height of ceilings, 8 feet. There are a hall, four chambers, a bed-room, and four closets. It will be seen that there is no waste room. The stair-landing or hall is in the center, and though occupying but little space, has five doors leading to the several apartments, besides one door opening to the garret stairs. Each of the rooms is of fair dimensions, and has abundant window openings. The head-room for the main stairs is partially taken from the bed-room floor, forming an angle, with clear head-room from the ceiling below to the face of the partition seen to cross the stairs.—This angled portion is "squared up," forming a shelf in the bed-room.... **Attic**.—The plates show 2 feet, and the center 11 feet above the floor. The whole is floored over roughly for storage, etc.... **Construction**.—The cellar and first story walls are of broken stone laid in best mortar, in the cellar 18 inches thick, and in the first story 16 inches. All sills and lintels are of blue stone. The frame is of sawed timber of sizes indicated in the estimate. The siding for the upper portion is clap-boards, laid on sheathing boards of even thickness. The roofs are of shingles laid on spruce lath. The inside flooring is of 8-inch spruce tongue-and-grooved;

outside of 4½ inch pine. The cellar windows have three lights each, and are hung with butts; all other windows four lights, hung to balance weights with best cord. All doors are of pine, panelled and molded. Plumbing as described in *American*

Total.	\$2,000 00

### The Jersey Cow "Eurotas."

In April, 1873, Col. R. M. Hoe, sold out his herd of Jerseys. They were chiefly, perhaps entirely, of his own importation and breeding. The sale was widely advertised, and largely attended, and Mr. A. B. Darling, of Darlington, N. J., the well-known host of the Fifth Avenue Hotel, paid the highest prices, and bought the best animals. For "Vesta," (1235), an imported cow, bred by Lord Rokeby, and of the Dauncey Stock, he paid \$700. For "Leda" (799), a daughter of "Jupiter" (93),

2nd," was no doubt a very well bred bull. He showed it in his appearance, and proves it in his get. "Europa" was the result of close in-breeding, a strong, vigorous, healthy animal, showing not the least evil results from such near couplings. She is still alive, breeding regularly, and was sold in May last, for a high price. "Rioter 2nd" was therefore an entire, and strong out-cross upon the "Alphea stock." The result to be expected, was that the offspring would possess those qualities, for which the parents had been bred, in an intensified degree. "Europa" was not a very extraordinary

which, if kept by itself, might prove them the peers of even this wonderful cow?—A question which, though it cannot be answered, is not the less worth considering. Col. Hoe made to the writer an interesting statement of how he came to import Jerseys, and such Jerseys. His first importations of cattle, were two Shorthorns, and one Devon, all pure of course, and when showing his little Devon cow to Mr. Edward Faile, whose Devon herd was at that time the best in the country, he told him that if he wanted cows of a pure breed for "Brightside,"—his beautiful country place, now within the

THE FAMOUS JERSEY BUTTER COW "EUROTAS," (2,454).

and "Alphea" (171), he paid \$640. For the bull "Sarpedon," a son of "Mercury" and "Europa," (own brother and sister—by "Jupiter," out of "Alphea,") \$630. With these he bought "Eurotas," (2454), for \$325. She was three years old, half sister to "Leda," and not so handsome.

Mr. Darling was disappointed in the performance of "Vesta." "Leda" proved with him an excellent butter cow, but was surpassed by her half-sister, which is the subject of this sketch. "Eurotas" is the daughter of "Rioter 2nd," a bull imported by Col. Hoe, bred by the Marquis of Bristol, and descended from the famous Dauncey herd, and "Europa," a daughter of "Jupiter," out of "Alphea," his full sister, they being by "Saturn," out of "Rhea," both imported by Col. Hoe, directly from the Island of Jersey. "Eurotas'" pedigree, so far as we know it, therefore runs thus (imported animals in Italics):

Eurotas 2454	{	Rioter 2d, 469, bred by the Marquis of Bristol.	
		Europa {	Jupiter 93 { Saturn 94
		179 {	Rhea 166 { Saturn 94
		Alpha 171 {	Rhea 166

A short pedigree, but an instructive one. "Rioter

milker or butter maker, so far as known, (perhaps she has never had a first rate chance), but "Alphea" was, and so was "Rhea," doubtless also there were extraordinary milkers and butter yielders in "Rioter 2nd" line, for the Dauncey herd was bred with extraordinary care, both for color, and for excellence at the pail. "Eurotas" has been bred as a "winter cow," that is, to calve in the late autumn, or early winter, and though yielding well, does not come to her full flow, and yield of butter, until grass comes. This is remarkable, that a cow calving in December, should give more milk in May, than at any time during the winter, but so it is with "Eurotas" this year, and the same was true last year, though less accurately observed. The extraordinary production of butter of this cow, was not observed until about two years ago. She is not handsome, though well shaped; in fact, has the ideal form for a milch cow, not exaggerated. She was bought at a lower figure than the other cows, and for this reason great things were not looked for, and her milk went in with that of the common herd. How many cows are there whose milk is thus mixed with that of others,

limits of the City of New York—he would advise Mr. Hoe to settle upon Jerseys, and that if he would import a heifer more than he wanted for himself, on his next trip, he would take one. This Mr. Hoe did, and being referred by a business friend in London, to Lawrence P. Fowler, the younger member of the firm of Michael Fowler & Son, he gave him a *carte blanche* order for half a dozen heifers and a young bull, to be selected with care, and shipped within six months. Richardson, and others, were importing Jerseys to New York, and limiting Mr. Fowler in his purchases to £5, or \$25 a head, first cost. The six heifers and bull cost Col. Hoe between 18 and 19 guineas each, on an average, besides commissions. The famous animals of this importation were "Saturn," "Rhea," and "Edith." Mr. Faile was offered first choice, but declined it, and Col. Hoe's manager selected "Rhea," Mr. Faile taking "Edith." It was stock tracing to this cow "Edith" (167), which being crossed with bulls of the "Alphea Family," brought the high prices at Mr. Kellogg's recent combination sale.

The animals of Col. Hoe's importation, were without doubt much better selected, and worth

more than those which American breeders were at that time familiar with. Those which were selected in England, proved exceedingly good. They were the progeny of animals bought on the Island for English breeders, and selected doubtless in much the same way. The dealer taking time, making his selection, and paying the farmer's price. The rules of the Am. Jersey Cattle Club exclude these English bred animals now, unless they can be traced back, animal by animal, to the Island. Why this rule should prevail now, to exclude such animals as "Rioter 2nd," and "Vesta," we do not know, and certainly it seems unwise; and how it comes that these animals, tracing simply to the herds of well-known, reliable English breeders, were admitted to registration, does not appear.

"Eurotas" Butter record has been repeatedly given for one week, namely, 23 lbs. 6 ounces. She has been tested this year since her calving in November—the test beginning Nov. 10th.—Between this date, and April 10th, she yielded 364 pounds, 15 ounces of butter, according to a statement published by Mr. P. C. Kellogg. From him we obtain the results to June 10th, as given herewith.

For five months ending April 10.....	364 lbs. 15 oz.
" the month " May 10.....	73 lbs. 13 oz.
" June 10.....	91 lbs. 9 oz.

So far, in seven months from calving. 530 lbs. 5 oz.

This last monthly statement shows over three pounds of butter a day, for the seventh month after calving, and about the fifth of pregnancy. For the last day of the record, the amount of butter is estimated, being taken at half that of the two previous days. Churning is done on alternate days, that of the 9th and 10th being churned together.

The portrait we present, is copied from a painting by Mr. H. S. Kitteridge of this City, kindly loaned by Mr. P. C. Kellogg, and is a most accurate picture of the cow. It is hardly necessary to direct attention to her characteristic wedge shape, heavy at the rear, and thin and delicate forward, or to the enormous lacteal development, or indeed, to the roomy frame, and capacious abdomen, offering plenty of room for the digestive and assimilative apparatus, which must be in the very best order for such work as she is doing with ease and enjoyment all the time. "Eurotas" is of a brown color, lighter upon the legs and ridge of the back, where it approaches gray. She is an animal of excellent constitution, as shown by her form, and proved by her performance. She is thick through the breast, having a deep sound chest, good muscular development, and excellent under pinning. She will do well on a mountain pasture, in all weather, and no doubt equally well stall fed, and with little exercise.

### Among the Farmers.—No. 55.

BY ONE OF THEM.

I was greatly distressed by the drouth this spring. My oats were set back wonderfully, though in good season, and as I have had rather poor luck in seeding with spring grain lately, I concluded to sow no grass-seed, but cut early and sow grass with turnips on the oat stubble.

The rag-weed and smart-weed made their appearance early among the oats and, of course, grew in spite of the dryness of the soil. I was led therefore to my first experiment in

#### Harrowing Growing Grain.

I used a Thomas' harrow, and the soil was like an ash heap. There had been corn on the ground last year, on part of it at least, and the stalks were not all covered and there were a few stones. Where the harrow teeth caught a corn-stalk destruction was wrought, apparently at least, and a loose clod or stone, or any thing that would drag, made havoc also. Where the harrow ran unimpeded it was bad enough. I could not sit on the harrow—that made things look too bad, but I did make two or three bouts for experiment sake. The Thomas' harrow, consisting, as it does, of three small harrows drawn abreast with a seat for the driver straddling over them, so that if the driver sits in the middle, the pressure of his weight will bear evenly upon all, is not handy to turn sharp corners with, and I found I could leave unharrowed half-moon shaped patches

in the corners much easier than not. In a few cases I did so for the sake of comparison.

A sorrier looking field of oats I never saw than that was after once going over. I felt sick, and my man, Michael, held up his hands aghast.

We had one or two scorching days. The weeds, still very small, were killed where ever sufficiently disturbed. Then we had a fine shower, and the prostrate crop revived wonderfully. The result upon the weeds was so satisfactory, that after harrowing the potatoes just showing the rows well, in part of the same lot, I put the harrow on to the oats for the second time, still leaving some of the corner patches which were missed by the harrow the first time. The oats were six to ten inches high, measuring the full length of the leaves of some that were torn out. If I regarded it a piece of heroism to go on after the first bout at the first harrowing, it was doubly so the second time, and I hesitated seriously. One crop of weeds had been pretty well killed, another was just showing itself in the seed leaf, having sprung up after the shower, but the oats were so large, I argued, that these will never have a chance at light and air until after harvest, and then they will be plowed under. I resisted temptation and harrowed away. The crop looked worse than ever, and seemed to pick up very gradually during the excessively dry weather. We had rains after a while and it started and soon looked as if nothing had happened, and now, June 12th, is a pleasure to behold. I have never had a grain crop so free from weeds. Another year I will plan to harrow four times at least, especially if the weather be moist. In dry weather the weeds are most effectually killed, but more of the oats are dragged out too. I have heretofore reported the experiments of my neighbors in harrowing grain, but this is my own, and as the results tally well with those previously reported, I am well satisfied to inaugurate the new practice and follow it at least until we get to hoeing grain, which I well believe is superior practice.

#### Big Horses.

There is a remarkable change in the size of loads drawn in our principal cities, especially in Boston and New York. Boston has taken the lead in this matter, and her buyers have picked up blocky, heavy horses all over the country, while New York has been satisfied with highth. The leggy, sixteen to seventeen-hand brutes which we see here would not sell there, for they go all for weight. For steady draft, large slow moving teams do their work more economically than quick moving ones. It is far better to go once with a heavy load than twice with light ones. It is your comparatively small, quick going, nervous horses that balk. Sometimes a heavy horse will refuse to draw, but rarely.

At the French sale stables they put a horse—any draft horse they have to sell—before a dray with locked wheels and make him draw it, or at least do his "level best," scratching like a cat, the fire flying from the pavement, to show that he will not balk. Where they sell draft horses in this country they make them trot off to show their fine action and style. But we are learning fast, the Pereheron, Norman, and Clydesdale stallions that come over on almost every steamer, are fast making a change and the trucks are getting larger every season. Now we need better pavements and better country roads, so that we can use the enormous power of these large horses to the best advantage. I was speaking about them to Thomas Galbraith, formerly manager for Mr. Thorne at the time he had the famous Duchess Herd, and he told this story about

#### London Truck Horses.

Mr. Galbraith took two large bulls, "Lord Oxford," and one of the "Thorndale Dukes," I believe, out to England for the purchaser. He lauded in London and wanted to get them across the city to a railway station, distant about three miles. Rather than lead them over on the always slippery pavements he concluded to put them on one of the low-hung truck, or platform, wagons which they use for moving heavy freight, like molasses and sugar hogsheads. The owner of a line of one-horse vehicles of this character on a stand, named 14

shillings (\$3.50) as the price he would let him have a truck for. "Is not that a high price?"—"No, it's right, they're good horses," said the truck owner.—"Well," said Galbraith, "I will give them a pretty good load."—"See here," said the other, "if you mean to put over *three tons* (6,720 pounds) behind one of my horses for that trip you can't have them at all."—When afterwards Galbraith came along with the two bulls, one weighing 2,400, and the other 2,200, standing together on the platform drawn by one horse, he was greeted: "Ha-ha! Is that what you call a 'pretty good load'?"

We will come to this one of these days in this country, but we must have better roads, heavier horses and stronger trucks. It is rare to see over three tons behind a pair of horses in New York. Six-ton loads are certainly as frequently seen in Liverpool and London as loads of half the weight are here.

#### Feed for Butter.

At this time when so much attention is given to butter production, we are naturally on the lookout for fodder that will improve both the quantity and the quality of that product. Corn fodder holds a deservedly high place as milk-producing food, but the quality of the milk is thin unless meal be added to the stalks, or fed in connection with them.

Mr. L. W. Ledyard, of Cazenovia, Madison Co., N. Y., has a fine herd of Channel Island cows, both Jerseys and Guernseys, and finds that Golden Millet fed to his cows produces a marked change in the quality of the butter and probably also in the quantity. The butter comes much firmer and of a more granular and waxy texture. I did not have the opportunity to question Mr. L. very closely, so as to learn his full experience. He has, however, established the fact to his own satisfaction that this is the best food he can give his cows to secure the best quality of butter. I would have been glad to know how Hungarian or other millets compared with it. The comparison in Mr. Ledyard's mind was clearly as between hay and corn fodder, and Golden Millet. Wheat bran is a milk-making food, but it does not increase the butter very much. Cabbages and turnip tops increase both the milk and the butter, but do not improve the flavor. Parsnips and carrots certainly and largely increase both the quantity of the milk and yield of butter, and improve the quality of the latter. Sugar beets and mangels are among the best milk producing articles of bovine diet, and the quality does not suffer so far as I know. How important it is that we should have experiments, yielding definite and valuable results. I believe the New York Legislature passed a bill for

#### An Experiment Station

at the last session. Efforts had been made before for an appropriation for such an end, and now we presume we may give the credit to the known interest of the Governor in the institution named in honor of his father, and which in the popular mind has always been an Agricultural College. The success of such an "Experiment Station" does not depend upon appropriations, though money is always necessary. It too often happens that money easily obtained, as by vote of a Legislature, or Act of Congress, is easily spent, and that without accomplishing the ends intended. When such an institution grows by its own necessities, under judicious management, it is sure to accomplish great good. There are hundreds of problems presenting themselves to the thinking farmer, and student of agriculture, which can only be answered on the farm, in the feeding stalls, or pig pens, in the dairy or in some other practical way; where the land and the manure heap, the live stock and their products, the chemical laboratory and microscope, and the whole range of philosophical instruments from rain-gauges to lactometers, in one way or another, in good earnest hands, cooperate to bring about valuable results.

**Preparation for Fall Crops.**—There is the good and the poor way of preparing the ground for the reception of the seed of the crops sown in the fall. The large average yield of the wheat crop of England is due in a great measure to the great care

taken to prepare the ground for the best growth of the wheat plant before the grain is sown. The fields that are imperfectly plowed and indifferently harrowed are far too common with us, and until the soil is made deep and mellow by thorough tillage, all the manure and artificial fertilizers we may apply will not bring the yield of our fall sown crops to the most profitable point. A little extra work in preparation will many times bring a large margin of profit when it comes to gather the harvest.

### Tenant Farming.

In the Eastern and Middle States there are thousands of farmers of small means who either can not, or do not wish to, "go West." These must occupy rented farms, and, in many cases, be content to do so for a long term of years. Under the present revival of interest in agriculture, and as methods of cultivation grow more elaborate and expensive, the tendency will probably be towards an increase of this class; and, therefore, much of the farming of the future, in the section named, will depend for its success on a satisfactory working of the landlord and tenant system in some form. Why should not the co-operation involved in working a farm "on shares," for instance, be as satisfactory and profitable to both parties, on an average, as other partnership? I assume that it is not generally a success, that being the prevailing impression, and it becomes important to know whether the reasons for failure may not be removable. Why should not tenant farming with us do, not only as well for both owner and farmer as is usual in England, but better, because of our superior advantages in climate, markets, etc.?

There are large amounts of capital in the East looking in vain for investment at from four to six per cent. There are also thousands of farms within easy reach of our seaboard cities, that instead of being worked are "mused," as a Jersey friend of mine puts it, the condition probably standing at its worst, as a rule, where the occupant is a tenant. Now, is this situation without remedy? Why would it not pay for men who have capital and some knowledge of, and taste for, farming (although in other business), to buy these farms,—they are always for sale—rent to a first-class farmer "on shares," spend some money in improving the land, and "push things" generally? I say on shares,

Fig. 1.—DYNAMOMETER, OR FORCE-MEASURER.

because, under the present condition of farming, probably, with a fixed money rent, the temptation would be for the owner to neglect and for the farmer to "skin" the land. It seems reasonable that such a double team should be able to do much more with a farm than any one party of moderate means. I should be glad to see some comments and criticisms on these points. If it can be shown that much of the capital now made a foot-ball of in

Fig. 2.—ELLIPTIC DYNAMOMETER.

our large cities, can be profitably put against the skill and labor of farmers who have means to properly stock and work a farm, but not sufficient to buy it, I think a long step forward will have been made in the agriculture of the Eastern and Middle States.

PHILADELPHIA.

### Dynamometers, or Force Measurers.

The working of all machinery requires power or force, and it is of great importance to be able to

Fig. 3.—DYNAMOMETER, IN COMPACT FORM: S, S, spring; F, cross-lever.

measure this force. To this end Dynamometers have been constructed. The simplest form of the power or force-measurers—for that is the meaning of their name—is shown in figure 1, and consists of a coiled spring encased in *b*, bearing an index, *a*, which moves along a graduated scale as the coil is extended. One end of the Dynamometer is fastened to the object upon which the force acts, as a plow or mowing machine, and the other is attached to the source of the power or force; the horse, ox, or steam engine. It is evident that this instrument in its simplest form is only a very strong and heavy spring balance, and is used for "weighing" the force exerted by a horse, for example, instead of the pull of gravity as the balance does in simple weighing. The amount of force to draw a plow, for example, is shown by the place the index takes upon the scale. A second form of Dynamometer is shown in figure 2. The ends of the oval spring, *Q*, *Q*, are attached to the draught and object drawn. The greater the force exerted the nearer the sides of the spring will be brought together, and the amount of power is shown by the pointer, which is moved along the scale by the rod, *E*, pressing on the base of the pointer. A third form of Dynamometer is shown in figure 3, bringing the spring, *S*, *S*, and the graduated scale near together, thus making the instrument more compact. In the first and

second forms there is a great inconvenience and lack of accuracy arising from the rapid vibrations of the index caused by the unequal resistance of the object at different moments, and the unsteady motion of the horses. The trouble is removed in the third kind, by attaching to one end of the index, *E*, a piston which works in a cylinder, *C*, filled with oil. The piston has a small hole through which the oil passes from one side to the other as the draught varies and causes the piston to move, and does away with any sudden or jerking motion. A more accurate instrument is the Self-recording Dynamometer, which marks all the vibrations upon a strip of blank paper by means of a pencil fixed on the index. The paper is moved along slowly by being placed on two rollers, one of which unwinds the paper upon the other. The rollers which carry the paper are turned by a wheel running on the ground, and giving its motion to the rollers through an endless chain, and working the cogwheel of an endless screw. A Self-recording Dynamometer is shown in figure 4, and a portion of the paper showing the record is given in figure 5; the short lines, *a*, *b*, show the quick changes of the index. With this attachment a permanent register is made of the force required for the working of different implements, and with an accuracy beyond dispute.

The importance of a force test in deciding upon

the merits of a plow, mowing machine, etc., is greater than it might seem at first sight. Two plows may do the same work, and do it equally well; but the Dynamometer may show that one requires a fourth more force than the other. There would be a great saving in such a case in buying the plow with the lighter draught. Figure 6 is the Dynamometer now much in use; it is strikingly simple in its construction, as the illustration shows, and made by Fairbanks & Co., of "Standard Scale" renown. These instruments range in capacity from 600 to 2,000 lbs. We do not claim that the measurement of the force by the Dynamometer is perfectly accurate, but it is acknowledged as an instrument of great value in testing the draught of machines, and to its use in the various trials of mowers, reapers, plows, etc., at fairs and elsewhere, we are doubtless indebted to the great improvements in lessening the draught of farm implements. When the test is made with great care, and the

trials are of sufficient length and variety, there is no other method equal to that of the Dynamometer.

**Autumn Seeding to Grass.**—It is the general custom to seed to grass after some grain crop, as wheat, oats, or barley; but when it is desired to get a field into grass in the quickest possible time, this practice need not be followed. Grass and clover seed may be sown this month with the probability of success. This is not without its risks; a dry spell may prevent the Fig. 4.—SELF-RECORDING DYNAMOMETER. seed from germinating until the season of growth is pretty well passed, when only a poor "catch" will be obtained. A shelter to the young grass and clover plants that will protect them from the hot sun, and at the same time prevent the soil from becoming too dry, is very desirable. For this purpose no crop is better adapted than white turnips, which grow quickly, and with their broad leaves make a protection to the grass seed and young plants, and shade for the soil. For the good of the grass it is not best to have the turnips grow very large, otherwise there may be danger from smothering; but a fair yield

Fig. 5.—MARKINGS OF THE SELF-RECORDING DYNAMOMETER.

of turnips may be secured with no danger to the grass. The turnips should be pulled early, at which time the clover will be well started, and will soon thicken up and cover the ground before win-

Fig. 6.

ter sets in. With a good dressing of manure, an early start may be secured in the spring, and a good crop of hay or a fine pasture results. When the soil is continuously moist, deep and mellow,

the grass seed may be sown alone; but in most cases it is safer to provide a shading crop, like the turnips, besides a good return for the preparation of the soil is at once obtained in a valuable crop of roots for feeding the stock in autumn or early winter.

### The Sheep Rot, or Liver Fluke.

The wet season of 1879, in England, has been followed by an unusually fatal out-break of the "Rot" among sheep. At five other dates during the present century, wet seasons have preceded visitations of this very destructive disease, namely: in 1808, 1817, 1824, 1830, and 1853. The association in time of the prevalence of the "Rot," with a season of unusual rain, is enough to suggest that there may be some direct relation between the two. Through investigations of such naturalists as Dr. Cobbold, Von Siebold, and others, the precise nature of the Sheep Rot has been discovered, and the relation between the wet season, and the unusual abundance of the disease established. The "Rot" is caused by a parasitic animal known as *Distoma hepaticum*, which takes up its abode in the ducts in, and leading to, the liver, and hence popularly called Liver Fluke. The Fluke is a sucking worm resembling the leech,

Fig. 1.—THE FLUKE, FULL SIZE.

of a flat, oval shape, thick and rounded at one end, and provided with a sucker or mouth. The full-grown parasites are shown, separated from the liver, in fig. 1, and small ones, but partly grown, are represented in fig. 2. These little animals are quite highly organized, being provided with a digestive apparatus, and a branched intestinal canal, fig. 3, and a system of veins and blood vessels, shown in fig. 4. The life-history of this parasite, about which in former years there was much conjecture, and even dispute, is now thoroughly understood. The mature Fluke, as found in the sheep's liver, is the end of a series of transformations, which we will trace from the egg of the perfect Fluke, through its changes, around to the full grown Fluke again.

The egg, after leaving the Fluke, finds its way into the intestines of the sheep, and is expelled with its excrement. If the egg falls upon dry soil, and no water reaches it, it soon perishes; if, however, the egg meets with sufficient moisture, it soon hatches into a small embryo, which is propelled by minute hair-like appendages. In a short time legs are provided, and the young Fluke becomes a crawling "worm." In this form it gains entrance to the body of some snail, and begins its parasitic life.

Fig. 2.

Fig. 3.

Within the flesh of the snail, the Fluke becomes encysted, or enclosed in a kind of sac, in which state buds are formed, which, breaking away, leave the snail, and become like small tadpoles, moving about by means of their long slender tails. These again enter the snails and become parasitic, and afterwards encysted for the second time. In this pupa, or resting state, the Fluke is conveyed from the grasses, upon which the sheep feeds, into the stomach of the sheep, and once there, the final leech-like state of the parasite is quickly assumed, and finding its way into the gall ducts of the liver, it reaches its last state, and does its most destructive work. With this sketch of the development of the Fluke, it is easy to understand the relation between a wet season, and the prevalence of the "Rot" in the season following. The hatching of

the egg of the Fluke is dependent upon the presence of a considerable amount of moisture when it is passed from the sheep and falls to the ground. The young Fluke afterwards must enter the snail, but the snail lives only in water, or in very moist localities. In wet seasons, the number of such localities is extended, the number of eggs that hatch is greatly increased, as is the number of snails, bearing the parasite in its first stages. The

Fig. 4.

Fluke often occurs in sheep, without its presence being suspected. It is only when it is sufficiently abundant to produce "Rot," that attention is called to it. In the first stages of the disease, there is an increased appetite, and a tendency to fatten. This has been taken advantage of by the English feeders, who it is said have purposely "Rotted" their sheep, in hastening them on to the shambles. This unnatural excitement of the first stages of the disease, is soon followed by a falling away in condition; the color of the eye, instead of its usual brightness, becomes tallowy in appearance, the skin becomes wet, and the wool loose. As the disease advances, dropsy develops, and a watery tumor appears below the lower jaw; the whole system becomes deranged, and in a short time the sheep is the pitiable object shown in figure 5. This engraving of a sheep in the last stages of "Rot," as well as those of the Fluke, are borrowed from that excellent and practical work, Stewart's "Shepherd's Manual." When an animal reaches this condition, the end soon follows, and the sheep dies in a state of rotteness throughout.

**Remedy.**—Whenever the Flukes have found their way into the liver of the sheep in any considerable numbers, there is no practical way of removing them—death must shortly follow. Sheep may live, and even thrive when infested with Flukes to a slight extent; but the shepherd should always be on his guard against them. In the present case,

Fig. 5.—SHEEP AFFECTED WITH FLUKE.

the ounce of prevention is worth far more than the pound of cure, and therefore the flocks should be kept from feeding upon low lands, and never allowed to drink from pools of stagnant water surrounded by dense vegetation, as in such places the fluke-bearing snails abound. The Liver Rot is in one sense very much a question of drainage.—A recent article in the "Agricultural Gazette" (London) on this subject states that the "tender Merino sheep first falls a victim, while the Lincolns, or still stronger cross-bred, stand the best." The Fluke has prevailed to some extent in this country; there has been a recent outbreak of it in Oregon, and we should profit by the lesson of the very serious loss abroad, and strive to keep our flocks from the pest, especially in seasons of, and those following, unusual rains, by guarding them from feeding in low lands where the infested snails may abound.

**Curing Fodder Corn.**—The chief drawback with fodder corn is the difficulty of properly curing such a heavy crop of succulent green herbage. When it is remembered that 30 tons per acre has been reached, the problem of curing is seen to be an important one. The French system of ensilage may in time come to the rescue and provide a method of preservation that retains the fodder in its green state; but the introduction of such a system must be slow, and until then the old method of dry preservation must be practiced. The putting together of large quantities of half-cured stalks must be abandoned, as it has been the greatest source of loss to those who have grown fodder corn. The mow should be thoroughly ventilated

by shafts passing up through its center, and when the fodder is put in stacks, they should be of small size, holding but a few tons, and better still, provided with a shaft, made of a few boards, in the middle.

### Hints and Helps for Farmers.

**A CHICKEN COOP.**—Mr. L. Prentice, Leavenworth Co., Kansas, sends a sketch and description of a chicken coop, which is given in figure 1. The frame is made of pine. Three of the sills are one inch thick and three inches wide, the front one being one inch square, and let into the lower corners of the side sills. The ridge pole is one inch square,

Fig. 1.—A COTTON CHICKEN COOP.

and the rafters are made of lath. The frame is covered with common cotton domestic, put on with small tacks. Five yards of domestic will cover four coops, and last two or three years if housed when not in use. Such a covering excludes the rain, snow, and wind, yet the sunlight passes through, giving warmth and light. Mr. L. writes: "We have never lost a chicken from a rain or snow storm while in these coops, and we use no other. A group of them resembles a camp-meeting ground. When necessary to close up the coop, as at night, we set up a board in front, or set two or more together, thus closing each other."

**HEN'S NESTS FROM BARRELS.**—Mr. L. W. Grayson, Jefferson Co., Miss., sends his plan of making nests from barrels as follows:

Saw the barrel in halves through the line, A, A, figure 2, and then nail the hoops on to the staves securely. Saw the hoops through the line, B, B, and each part, when provided with a bottom, C, and cleats, D, D, to keep it in place, makes a substantial waterproof nest that can be fastened to a post or the side of a building. The nest complete, is shown in figure 3, and is attached to the base of a post.

2.—CUTTING THE BARREL.

**Barn-Yards.**—For good reasons the barn-yard is one of the most important features of a farm, and its proper keeping should be constantly in

Fig. 3.—THE COMPLETE NEST.

mind. The manure here saved or lost, in a great measure, determines the success or failure of all other farm operations. The chief points to be observed are cleanliness and healthfulness of the animals there confined, and the saving of all the ma-

nure that is produced by them. Both of these ends are accomplished by having enough bedding or litter to absorb all the moisture and cover the droppings. The yard should be so constructed that it is not washed by the dashing rains of summer, but being comparatively level the litter holds the excess of moisture. In this way a good supply of the best manure is made. The straw stacks that often stand by themselves in the open field should furnish the necessary litter for the barn-yard, instead of slowly rotting away where they stand.

### A Barn-Door Holder.

A simple apparatus for holding a swinging barn-door open at any point, was described to us in

A CHEAP BARN-DOOR HOLDER.

Livingston Co., N. Y. (We did not note down the name of the contriver—an aged farmer, who busies himself with making new devices for ordinary work.) This is a stick, 2 to 3 feet long, with an iron ring or thimble around the lower end, to prevent splitting. A sharpened iron rod of any desired length is driven in. The other end is supplied with a hook to catch into a staple driven into the door. When not in use, it is turned horizontally, and the lower end rests on a spike or wooden pin, as shown by the dotted line in the engraved sketch. A similar stick on the other side could be used, if it is desired to hold the door only partly open, instead of swinging it back against the side of the barn, or against a stray post or other object.

### A Rustic Seat, Quickly Made.

Among Mr. Judd's "Notes by the Way," we find a brief sketch of a Rustic Seat he saw on the shaded grass-plot around the residence at the farm of Wm. R. McNair, near Lima, Livingston Co., N. Y.—One end of a Linden (Basswood) log was found to be too knotty and otherwise unfit for sawing into boards. A piece 28 or 30 inches long was cut off with a cross-cut saw, for fuel. One of the daughters found a better use for it. First, at 15 inches from the lower end, the block was cut more than half through with a cross-cut saw. Then with an axe, and finally with a chisel, the seat portion was

A CHEAP RUSTIC SEAT.

split and cut out, as shown in the sketch. All this was accomplished in half an hour or so during the nooning hour, by a couple of the farm hands. The saw-cut under the arms will not affect the solidity of the arms. This might be filled with a bit of putty, or a mixture of dry clay and oil, to keep out water and prevent future decay. A small gutter somewhere in the seat, to carry out rain when falling upon it, would be useful. Such seats as these, quickly made at no cost, may be quite freely provided for door yards, fruit yards, shady corners, etc.

**The 17-Year Locust, or Cicada.**—This destructive insect, which, in the same locality,

makes its appearance every seventeenth year, is now exciting attention on a number of places in the United States. This brief description of the Locust is given in answer to the questions concerning it, sent to the *American Agriculturist*. The mature insect resembles the Harvest-fly, but its head is narrower, with red eyes and large wings the veins of which are orange red. The females are provided with powerful piercers, with which they make narrow grooves in the twigs and small branches of forest and fruit trees, and in which they deposit about 20 eggs, arranged in a double row. After thus laying 400 to 500 eggs, the insect dies. It is this cutting into the branches that is the source of damage done by the Cicada, as it weakens the limbs, causing many of them to break away from the tree during storms, etc. The males only are provided with a tightly stretched membrane, like a drum, which when made to vibrate produces the sound that, when coming from a large number, suggests the rumbling or dull, obscure noise of a threshing machine in operation at a distance. The eggs hatch in about six weeks, and soon after the larvæ or grubs drop to the ground. The larva is white and by the aid of its lobster-like claws burrows at once into the earth, where they feed on the roots of plants, during their long unnoticed subterranean existence of 17 years. When its "time is up," so to speak, the grub comes near the surface of the soil, and remains for a number of days in the inactive pupa state; after a while, the perfect insect comes forth through a rent in the back of the pupa-skin, and the circle of life of the Cicada is complete. A new deposit of eggs soon follows, branches are again destroyed, the dull drumming fills the land, and a second seventeen years of underground life is entered upon.

### Wood and Cement Water Pipes.

Mr. "F. S.," Brooklyn, N. Y., sends sketches and descriptions of cheap home-made water pipes

Fig. 1.—WATER-PIPE OF TWO PIECES.

to be enclosed in hydraulic cement. A wooden pipe is made of two strips of pine plank,  $1\frac{1}{2}$  inch thick by 4 inches in width; these are hollowed out in the center by a molding machine and the two pieces joined together to make a tube, as shown in cross-section in figure 1. The strips should be

Fig. 2.—WATER-PIPE OF BOARDS.

about 12 feet in length, their ends are cut square, and they are put together joined end to end, by means of a ring of galvanized sheet iron—a ferule of such iron as stove pipes are made of. These ferules are three inches long; one of them is placed between the ends of two sections of plank pipe, which are driven together, when the ring will have the position shown by the dotted ring in figure

1. In this way a secure water-tight joint is made. The two halves of the pipe are fastened together by screws placed six inches apart. The pipe is now ready for its encasement of cement, which should be made of one part cement, two parts clean sand, and two or three parts small gravel stones. The pipe should be laid below the frost line and after being placed in the ditch the concrete as it is prepared should be put around it.

Another kind of pipe is made of inch pine strips joined as shown in figure 2. First nail together the

Fig. 3.—OUTLET TO PIPE.

strips *B, B,* and *C, C,* after which the boards *A, A,* are nailed on as shown in the figure. These strips give strength to the pipe; the nails, six inches apart, being long and passing well into the strips *B, B.* The pipe thus made which may have a "throat"  $1\frac{1}{2}$  to 2 inches in diameter is afterwards encased in the cement concrete, the same as pipe in figure 1. An outlet for the water from the pipe may be made as shown in figure 3. A piece of iron tubing of the length required, with a bend at the upper end is threaded at the bottom and made to screw into an iron plate, fig. 4, fastened upon the pipe at the point of outflow, below which a hole is bored through the side of the pipe; in fact the tube is screwed through both the iron plate and the wood of the pipe. An ordinary faucet may be made of the upper end of the iron tube.

Fig. 4.—IRON CAP.

**The Lettuce Mildew.**—Early last spring the complaints from the loss of the crop for forced lettuce, were so frequent, that we were induced to send out a circular asking for further information upon this important matter. The results of this investigation were published in an illustrated article in the *American Agriculturist* for April last, p. 148. Since that time other answers have come in, and with them the information that the trouble is much more wide-spread than we were led to infer from the replies up to the time of writing the April article. We there stated that: "From the responses to these questions, we infer that the Lettuce Disease is at present confined to the Atlantic States." Responses from the South, even so far as Southern Texas, inform us of its ravages in that direction, and a letter now before us states that the region of the Great Lakes has not escaped; in fact, the growers of early forced lettuce in Central Michigan, for example, have had, in some cases, their entire crop almost completely destroyed. There is no doubt that the disease is a fungus, and the important question is, how to meet it, or, better still, how to prevent its coming upon the early lettuce. With the closely related mildew upon the grape-vine, Flowers of Sulphur dusted on at intervals has been found an effectual remedy; but with the lettuce plant we are met by the difficulty that the foliage is the portion eaten, and the dusting of it with Sulphur would not improve its taste or healthfulness; in fact, without thorough washing, it would not be marketable. It appears evident that just those conditions that produce the most vigorous growth of the lettuce plant, namely: rich soil, heat, abundant moisture, etc., are those best for the fungus.

## The Family Cow—How to Keep Her.

[THIRD PRIZE ESSAY.]

For several years I had been experimenting on a small scale in soiling cattle, my area of land, however, was exceedingly limited, being only a portion of the kitchen garden of a city residence, but my success was, even in this small way, so satisfactory, that I determined at some future day to try it on a more extensive scale. My reading and experience convinced me, that in our favored southern climate,

### A Half Acre of Land,

intelligently cultivated, would produce a supply of food amply sufficient to support one cow throughout the year, and circumstances favoring, I determined to try the experiment. In April, 1876, I became owner of a lot 250 feet long by 120 wide in the rear of my premises—the greater portion having been used as a grass plot for a horse. I immediately began by fencing off a portion 120 feet by 200, running a wagon-way 8 feet wide down the center, which, with the space occupied by the stable (say 20 by 30 feet), left nearly 22,000 feet, or within a fraction of half an acre, for actual cultivation.

### The Land was a Sandy Loam,

covered with a thick sod of Bermuda and other grasses. Years before it had been cultivated as a market garden, but latterly given up to grass; it sloped to the south sufficiently to favor good drainage. In and around the stable was a goodly lot of manure, which, during April, was spread upon the land—some 40 cart loads. On the 20th of April, the land was thoroughly plowed with a two-horse turning-plow, and harrowed until finely pulverized. On May 1st, I planted one half of this land in

### Our Common Southern Field Corn,

in drills two feet apart, with the grains about one inch apart. The rows were lengthwise, to render after cultivation more convenient. On May 4th, sugar corn was put in one-half of the remainder, planting at the same distance as the larger variety. May 6th, the remaining fourth was sown heavily with German or "Golden" Millet, in drills 12 inches apart. Seasonable showers, followed by warm sunny days, soon produced a vigorous and rapid growth. On May 15th, a Thomas' harrow was run over the first planted corn, and six days after over the second planting, and over the millet. On May 30th, the corn was plowed, followed by a good hoeing. A fortnight later, a second and last hoeing was given. The millet was also hoed twice, after which the growth effectually shaded the ground, and thus prevented the growth of weeds. In the meantime I had repaired the stable, and had a large door cut into the side next to the original lot, and made

### A Stall for our pet Jersey Cow.

The floor was made of cypress plank, 3 inches thick, and sloped very slightly from the manger. By actual measurement of the space occupied by the cow—giving just room for her hind feet to clear the same, a trough, eight inches deep, and fifteen wide, was made to receive the urine and droppings. The stall was 4½ feet wide, the sides coming only half the length of the cow, and just her height. The manger extended entirely across the stall, was 12 inches wide at the bottom, and 18 at the top, and 12 deep, the bottom being 12 inches above the floor. The fastening consisted of a ½-iron rod, passing from one side of the stall to the other, along the center of the manger, and one inch from it. On this rod was a ring, to which was attached a short chain that ended in a snap-catch, to attach to a ring fastened to the head-stall,—the head-stall being made of good, broad leather. Usually, in turning the cow out in the morning, the head-stall was unbuckled and left in the stable; to fasten again was but a moment's work. By this arrangement the cow had full liberty to move her head, without any possibility of getting fastened by the halter. The bottom of this manger was made of slats, one half inch apart, so that no dirt could collect. For feeding wet messes, there was a box made to fit one end of the manger, which could be removed to be washed without trouble. With plenty of sawdust, costing only the hauling,

### Perfect Comfort and Perfect Cleanliness

were matters of course. Attached to the stable, but on my original premises, was a lot 50 by 50 feet, where, during pleasant weather, the cow was turned, but free to go in and out of her stall at pleasure. In this lot was a trough, connected with the pump, where a supply of clean and fresh water was always kept. Daily this trough was emptied and thoroughly cleaned. A cow may eat dirty feed occasionally, but see to it that the water she drinks is pure. Unless this is attended to, her milk is unfit for human food. The manure trough being supplied with sawdust, the urine, as well as the droppings, were saved and removed daily to a covered shed located in one corner of the lot, where it was kept moist, and worked over occasionally. Our Jersey was due with her second calf about the 20th of June, but was still giving milk in April and May. Her feed from May 1st to the 15th of June, was the run of a common pasture, with a mess twice daily of wheat bran and corn meal, with hay. On the 1st of June she was dried up for a brief resting spell. On June 15th we began cutting the sugar corn, now waist high. This was run through a cutter (making cuts ¾ of an inch), and fed to her three times a day, first sprinkling two quarts of wheat bran over the corn, and continuing the hay feed twice a day. At the same time

### She was taken from the Pasture,

not to go on again until this experiment was finished. On the 22d of June her udder was so distended, it was deemed prudent to relieve it by milking. This was done twice a day for three days. Here, at the South, there is a foolish prejudice against doing this, the belief being strong among the ignorant classes that it will cause the death of the coming calf. In some instances I have found it necessary to relieve the udder daily for a week before calving; I never knew any evil to result. On the morning of June 25th there was a fine heifer calf beside her. As soon as convenient the cow was milked thoroughly, and a bucket of water, with one quart each of corn meal and wheat bran stirred in, and a pinch of salt, was given her, and *nothing else* except water for 24 hours. At evening she was again milked to the last drop, and the calf left with her during the night. Next morning a small feed of three quarts of wheat bran, and one quart of corn meal, made pretty wet, was given her, and her udder again thoroughly emptied. After milking, a small feed of hay was given, and a pail of water placed near. The calf was separated from her, but within sight. At mid-day the calf was allowed to take her fill, and afterwards the udder stripped. At evening, as the cow seemed to be free from any indications of fever, or inflamed bag, she was given a full mess of corn meal, wheat bran, cotton-seed meal, and hay. Her calf took her supper, and the udder was again stripped; that night the calf was taken from her, never to suck again, as fresh milk in a city was too valuable to feed to even a registered Jersey. Having, in years past, lost several very fine cows from

### Over-feeding and Under-milking,

at calving time, I cannot urge too strongly what Col. Geo. E. Waring calls "high starvation" at this critical period in a cow's life. If a cow has been decently cared for up to the day of calving, she needs nothing but rest, quiet, and a light mash,—warm in cold weather—for 24 hours, and then but light feeding for two or three days. But be sure to *empty her udder completely* at least twice every 24 hours, and if the cow is a deep milker, then three times; with this treatment, the feed can be gradually increased to all that she will eat up clean. It is a very easy thing to teach a calf to drink milk, when one has seen the thing done. Next morning this calf was impatient for her mess of warm milk, so, after milking her dam, I took a shallow pan, and putting two quarts of milk into it, proceeded to give the first lesson in a calf's life, of doing without a mother. The process is very simple, you merely wet the first and second fingers of the left hand with milk, and place them in the calf's mouth, to give her a taste of what is in store. Repeat this a few times, then gradually draw the pan nearer her mouth with your right hand, using your left as above. When the calf permits your two fingers to

enter her mouth, raise the pan so that your left hand will be immersed, and the calf, by suction, will draw the milk up between the fingers. At mid-day, another mess of milk, and a second lesson was given; at evening a third. Next morning the process was repeated, but in this instance she did not need the fingers to guide her to what was good for her, she readily accepted the situation, and stuck her pretty nose into the warm milk, which rapidly disappeared to where it would do the most good. But with milk worth ten cents per quart, and cream seven times as much, it did not "pay" to use six quarts daily of rich Jersey milk in this way, so, after a fortnight's supply of the raw material,

### The Feed was gradually Changed

to sweet skim milk for two weeks, and then substituting hay-tea, the milk ration was cut down to two quarts daily. Beginning with a tablespoonful of cotton-seed meal, thoroughly mixed with the feed, the quantity was increased in ten days to one pint daily. At one month old, she was gradually taught to eat bran by stirring it in her food.

The preparation of hay-tea is very simple. Nice hay was run through a cutter, and taking an ordinary two-gallon pailful, boiling water was poured upon it, then covered and allowed to steep for 10 or 12 hours. It makes a most excellent food, and calves thrive upon it. The most stylish and vigorous calf I ever saw, was raised upon hay-tea, with bran and cotton-seed meal as here described. I enter thus fully into the best manner of raising a calf without its mother, for the especial benefit of my southern readers, where the thriftless habit of allowing the calf to suck its dam, oftentimes until a year old, so generally prevails. In this instance the little heifer got along nicely until two months old, when an aggravated attack of scours set in, but by timely doses of laudanum in a mess of warm gruel, poured down her throat twice a day, for three days, a cure was effected. In ordinary cases of scours, a change to dry food will correct it, but it is well to watch and not permit the disease to become seated. A few years ago, a very valuable young Jersey heifer, received from the vicinity of Philadelphia, was taken in this way, while undergoing the usual course of acclimation incident to northern cattle brought south, and the simpler treatment proving of no effect, I gave injections twice a day of rice-water and laudanum, besides drenching her with corn-gruel and laudanum. This was kept up for ten days, but we carried her safely through, and her present value amply compensates for the time and trouble expended. But let us return to the cow. On the morning of June 29th, we began giving her

### A Fair Feed of Green Corn,

adding to it wheat bran, and cotton-seed meal. On July 2d she was fed all the corn stalks she would eat, continuing to add bran and cotton meal, giving four quarts of the former and two of the latter, and this was her daily food, including the German Millet, treated in the same way, until September. The green food was given three times a day, but the bran and cotton meal added only morning and night. Occasionally a day's supply was cut early in the morning, and allowed to wilt before feeding, but in this, as well as in many other matters, my man-of-all-work did as circumstances permitted. His various duties about the place gave him but little time to reduce to an exact system the care and feed of a cow. She had a good stable, and got plenty to eat; received daily a good brushing, and was treated kindly. Yet, she was *our* servant (and a most faithful one she was), and we were not her's, or slaves to any arbitrary clock-work regularity. She was fed and milked at regular intervals, but beyond this it was not always convenient to have regular hours at her stable. We did not keep her as an exhibition of a model cow in a model stable, and to exemplify a model system of care and keep. Like thousands all over the land, we

### Kept Her Simply for the Profit

she yielded, in the way of milk and butter. It has often struck me, in reading the many suggestions and hints about how to keep a cow, to be found in our agricultural and live-stock journals, that were they all literally carried into practical operation, it

would take the entire time of two able-bodied men to attend one animal—one to be always on hand during the day, the other to serve at night. Now common sense is a good thing, even when applied to the management of cows, and my experience convinces me that the average man wishes to know only the cheapest and easiest way to have an abundant supply of rich, wholesome, and clean milk, and with pride enough in the possession of a good cow to furnish a good shelter and comfortable quarters. Beyond these, breeders of fancy and high-priced stock may go to any extreme, and find it a paying business in doing so, but the village or city owner of one or two cows, kept solely for his own use, can not afford to indulge in any of this "upper-tendom" style of cow life—it won't pay him. As a row of corn was cut and fed, the land was plowed, manured, and more corn (common field) drilled in thick, so that the ground for the whole summer presented the appearance of an experimental corn field, with

#### Corn at Every Stage of its Growth.

This was kept up throughout the months of July, August, September, and October. Indeed, the half of this yield was more than sufficient for keeping the cow in superb condition, so that much the greater portion was cut in the tasselling stage and cured for winter feed. After September begins, it will not do to sow corn here; the worms destroy it, but in our southern Bean, known as the

#### "Cow Pea,"

we have one of the very best of soiling crops. Sown either broadcast, or in drills, it does equally well—makes a rapid growth, and affords a tempting and nutritious food for cattle. It grows until checked by frost, and I know of no plant, save Indian corn, that produces more weight to a given quantity of land. In this instance, we fed it daily during October and late into November, before a frost put an end to its use in its green form. Anticipating a frost, it was cut and cured for winter feed; and properly cured, no hay equals it for cattle.

November 24th our cow went into winter quarters, and for her winter feed there was over 4,800 pounds of well cured corn-fodder, and some 1,500 pounds of good pea-vine hay—far more than she could possibly consume.

Early in December, after spreading over the land all the manure on hand, it was plowed again, with a two-horse turning plow, and sowed thickly to oats, harrowing them in. A seasonable rain gave them a good start, so they went into winter quarters in a fine condition—a good stand and vigorous growth. The cow now received

#### A Daily Ration of Corn-Fodder

and pea-hay, run through the cutter, and after mixing thoroughly three quarts of wheat bran and one quart of cotton-seed meal, was wet with water (warm in cold weather). This was given her in the morning, and the same quantity at evening. The corn-fodder and pea-hay for a day's feed was 15 pounds of each, more or less. On this food she was kept throughout the winter, giving milk of excellent quality, and in good quantity.

In February, she was tethered every fair day in the oats; and in March, was fed a good mess of fresh cut oats, still, however, keeping up the winter feed of corn-fodder, pea-hay, wheat bran, and cotton meal. About the first of April, the green oats fed was increased to

#### All She would Eat,

feeding three times daily, and the excellence of this diet was shown by a marked increase in the quantity of her milk. Though due to calve again in July, she continued to supply a family of ten persons with an abundance of milk. Late in April, when the oats were in the milk state, they were cut and cured for hay, making a little over a ton of good food.

Upon summing up the result, the following dollars and cents view of the experiment of sustaining a cow on a half acre is submitted. The labor expended in cultivation is not put down as an item of expense, as the carriage horse was used in plowing, and the hired man did the rest.

Dr.	
To 1,500 lbs. Wheat-Bran, at 90c.	\$13 50
" 200 lbs. Cornmeal, at 70c.	1 40
" 800 lbs. Cotton-seed Meal, at \$1.00	8 00
" 300 lbs. Hay, at 75c.	2 25
Total	\$25 15
Cr.	
By sale of 2,300 lbs. Corn-fodder, at 60c.	\$13 20
" 2,100 lbs. Oats, at 75c.	15 75
	\$28 95
Profit	\$3 80

But the profit above shown, does not express the real profit. A year's continuous supply of rich milk, in abundance, for a large household; cream for special occasions, and that best of luxuries, delicious home-made butter, and one hundred dollars for the little heifer when six months old, aggregates the chief results of the experiment.

For the best results in soiling, no crop compares, as far as my experience goes, with our Southern variety of Indian corn; on rich land it produces marvellously. I have raised it at the rate of over one hundred thousand pounds (or fifty tons) per acre. There is no difficulty in producing three crops in one season on the same land. But cattle need a variety of food in soiling, as in other forms of feeding. Oats are excellent, and come in early. Cat-tail Millet ("Pearl Millet") is a rapid grower, but cattle are not specially fond of it; they like German Millet better. Garden (or English) Peas make an excellent food; coming into use in March, and lasting to June. I remember one year I produced five crops for soiling, on the same land, in one year, namely: oats, three of corn, and one of cow-peas. The last named is a superb food late in the year, after corn has gone. I have never experimented with roots, nor am I aware of any being cultivated in the South as a soiling crop. Cabbages set out in September and October will be ready for feeding in December, and will, next to corn, produce the largest weight of green food. One year I fed them to a considerable extent, and found my cows were very partial to them. By beginning with cabbages in December, to be succeeded by oats in March, then peas, corn, and millet, to wind up in November with the cow-pea, a cow in our climate can be soiled every day in the year. "MOBILE."

GEO. G. DUFFEE, Mobile, Ala.

#### Whiffletrees, Doubletrees, and Draught.

It is not always desirable to have both horses of a team work equally hard, but when it has been decided what portion each shall do, the whiffletrees, and other means of attachment, should be so adjusted that the prescribed work shall be constant, with no opportunity for either horse to shirk his part. In order to secure this uniformity in the division of the work, no matter what the position of the doubletree, or "evener" may be, the draught

Fig. 1.—THE HOLES IN LINE.

pins must all be in the same line. This principle is best shown by diagrams, in which the doubletrees are unusually broad. Figure 1 shows a doubletree, in which the holes for the whiffletree, and that for the main draught pin, are in line. The direction of the draught is shown by the arrow. If the whiffletree holes are equidistant from the draught pin, it is evident that the two horses will have equal work to do, when the doubletree is at right angles to the line of draught. This equality is shown by the lines A and B, which are of the same length. When the doubletree is not at right angles to the line of draught—see dotted lines in the diagram—the whiffletree pins will still be equidistant from the draught pin. What one whiffletree loses in distance in moving forward of the main pin, the other loses in moving backward. The lines C and D, measuring the vertical distance of the whiffletree from the

main pin, are seen to be equal. With this form, the horse that keeps ahead of his mate, neither gains nor loses anything—the position of the pins, when all in a row, does not permit of an advantage. For the sake of securing the greatest strength for the amount of timber used, the doubletree is usually made with the main draught pin near the front edge, and the whiffletree pins near the rear edge of the "evener." The working of such a doubletree, is shown in fig. 2. It is evident, that so long as the doubletree is at right angles to the

Fig. 2.—MAIN PIN IN FRONT.

line of draught, there is no advantage for either horse; but the moment one end of the doubletree is swung forward, the equality is destroyed. Thus the lines E, and F, which represent the proportions of draught, are equal. Not so with G, and H; the rear whiffletree pin being much nearer the center of the draught than the forward one. In this arrangement, the horse that keeps ahead of its

Fig. 3.—MAIN PIN IN REAR.

mate, may not do more than a third of the whole work, and yet the distance from the main draught pin, to each whiffletree pin, is the same. With this form of doubletree, the amount which each animal has to do varies with every change in the position of the doubletree, and this is a source of annoyance to animals of high temper, if not of more serious difficulties. The effect of putting the main draught pin near the rear edge, and the whiffletree pins near the front, is shown in fig. 3. With the pins equidistant from the main pin, and the doubletree at right angles, each horse does the same amount of work, but not otherwise.

Let the doubletree take the position shown in dotted lines, and the perpendicular distance from the two whiffletree pins is widely different, as shown by the lines K, and L, which also represent in inverse order the amount of work each animal must do to keep the doubletree in its present position. The nearer the line of draught of one of the horses comes to the line of draught of both (the heavy line with arrow), the more that horse is obliged to draw. In this case, the farther ahead the horse gets the greater is the load thrown on him, and the laggard has a comparatively easy time. When it is desirable to give one horse the advantage, that can be done by moving its whiffletree pin out, or that of his mate's in towards the line of draught; but it is not best to have the three draught pins out of line that the horse may get and keep an advantage when he does not deserve it.

**Selecting Seed Corn.**—It is as important to make a good selection of the seed that is to produce the next crop, as it is to choose the live stock that will grow the future herd. The selection should not be left until the time of husking, but be done now. Go through a portion of the field and select those stalks that are well eared and unusually vigorous—in fact, the best the field affords—and give them an extra chance for further development by removing the other stalks from the hill. Anything that will increase the vitality and perfect the development of the grain that is to be planted for the next season's crop, should not be

forgotten. We would seek for stalks with one good ear, rather than those with two small ones.

### A Milk Sink or Cooler.

Mr. "W. H. B.," Cecil Co., Md., sends a description of a home-made "Milk Sink," as he calls it, which he holds as superior to any other he has seen. As it is not to be secured by a patent, we present it to our readers. A brick box is built 6 feet long, 8 feet wide, 24 inches high inside, and the walls the

The lid of the sink should not be put down tight until the new milk is perfectly cold. A large button fastened on the edge of the wooden eap will serve to keep the cover up sufficiently to allow the air to circulate freely. When the milk is cold the cover is closed, and the Sink is left to itself until it is time for skimming or putting in new milk. The Sink described is large enough for 15 to 20 cows. With a large dairy it might be an improvement to have a partition about one-third of the way from one end for new milk, as the cans containing it

shown in the accompanying engraving. The excavation in the center of the room is the freezing tank which contains an uncongealing bath. Molds are placed into this bath which contain the water to be frozen. The bath is cooled to a low temperature, by means of the volatilizing liquid, which is caused to vaporize within tubes that pass through the bath. The vaporization is greatly increased by having the air partially exhausted from the pipes; in other words, there is a partial vacuum in which the vapor is rapidly formed. The latent heat of

AN ARTIFICIAL ICE MACHINE—PORTION OF ROOM SHOWING THE PROCESS.

length on one brick ( $8\frac{1}{2}$  inches) in thickness. There are pieces of wood the size of the bricks placed in the top layer of bricks, in the four corners and in the middle of each side, for the purpose of fastening a wooden eapping, thus making the walls secure. The "box" thus constructed is shown in figure 1. A lid is then made of thin boards, and fastened on one side by stout leather hinges, with a handle on the middle of the front side to raise it by. See figure 2. It is necessary to state that the brick-work is laid up in hydraulic cement, and to insure from any danger from leakage, two coats of cement are put on the inside of the Sink. Two

Fig. 1.—THE BRICK-WORK.

small outlet pipes are put in one end of the Sink, one near the bottom and the other near the top. They may be of iron  $1\frac{1}{2}$  inch in diameter, and are closed by simple plugs at the outer ends. It would be well in the construction of the Sink to have one end a little higher than the other, that the water may all flow out the lower pipe when desired. The cans that Mr. B. uses are made of "3x" tin, 18 inches deep and  $8\frac{1}{2}$  in diameter, holding 20 quarts. Two strips of thin iron are soldered across each

Fig. 2.—SHOWING THE COVER.

other on the bottom of the cans, to keep them from wearing out; they are provided with covers, and bails to lift them by. When all is ready, fill the Sink with water until the cans will nearly float. If possible have the Sink near the pump, or so that the water may be conveyed in a pipe. Mr. B.'s arrangement is something like that shown in figure 3.

should have more room than those containing cold milk. "When straining the new milk into the cans always do it outside of the Sink, as there is otherwise more or less spilling or spattering into the water, and in warm weather it might cause the Sink to become sour and smell. Cleanliness is about half the battle in first-class butter-making."

### Artificial Ice and How it is Made.

When the temperature of water falls to 32 degrees Fahrenheit, or zero Centigrade, it passes into the solid state—in other words, it freezes and becomes ice. In most parts of the earth, this formation of ice takes place naturally to a greater or less extent. During nearly half of the year, ice is one of the most common objects in the temperate regions of the earth. Ice, formerly regarded as a luxury in warm weather, has so many economic uses, that it has become a necessity, and the capital invested in collecting and preserving it, could we know its amount, would be immense. The question of producing ice artificially at any time, and in places most needing it, is a most important one. The working of the various ice machines, depends upon a well known principle in physics, namely; When a body changes its state, *i. e.*, a solid becomes a liquid, or a liquid becomes a gas, heat is taken up, and consequently cold is produced. This principle is illustrated in various ways. If we cause ice to melt by placing salt with it, there is a great absorption of heat, or a production of intense cold. A certain amount of heat is necessary for the existence of water as a liquid; when we would convert it into a solid again, we abstract that heat. The amount of heat disappearing in these changes is said to be *latent*, or hidden in the liquids. So in the change from a liquid to a gaseous state, or a state of vapor, heat is similarly taken up. This is nicely illustrated in the pouring of a little ether upon the hand—as it volatilizes, heat is absorbed from the hand and a sensation of cold is experienced. There are a number of liquids that, like ether, are very volatile, that is, pass readily into the form of vapor—such as Ammonia, Sulphurous Oxide, Ethyl-Sulphurous Dioxide, etc., all of which are now more or less used in the artificial production of ice. In the various processes one of these very volatile liquids is made to take on the gaseous state; to do this it must have heat from some source, and it is so arranged that water shall supply this needed heat, and in so doing it becomes solid, or ice. The details of the method vary, depending upon the liquid used, but the construction of the apparatus is essentially as

vaporization being constantly taken up from the non-freezing bath, reduces its temperature; that in turn absorbs heat from the molds containing the water to be frozen. The vaporizing liquid is kept in constant motion—being used over and over again—by means of an exhaust and compression cylinder in connection with a steam engine, shown in the rear of the room. The non-freezing bath is also kept in motion by the engine. When the water is frozen, the mold containing the ice thus formed is raised from the bath by means of a crane and pulleys, as shown in the engraving, and the ice removed, when the mold is again filled with water.

The same kind of apparatus is now used to some extent, for cooling rooms in which fruits, vegetables, meats, and other perishable articles are stored. Instead of having a large bath tank for

Fig. 3.—THE SINK COMPLETE.

the reception of ice molds, the cold, non-freezing liquid is forced through long tubes in the cooling room, and in this way the storehouse is cooled.

The practicability of the artificial production of ice is demonstrated beyond a doubt, and it may be well for those farmers, etc., who are so located that a supply of natural ice is not at hand, to look into the matter of ice machines. The machines are made of very many sizes to suit the trade, ranging all the way from a capacity of a hundred pounds to several tons of ice per day. A number of farmers might combine and a single small machine would furnish them all with the ice needed, and could at the same time be used to cool a store room for the keeping of fruits, meats, and vegetables.

We are indebted to the New York Ice Machine Co. for the engraving herewith presented.

### The Houseleek—Umbilicus.

Among the plants well suited to grow upon rock-work, are the Houseleek and other closely related plants. Those who are fond of odd forms of vegetation, by planting a rock-work exclusively with the various species of *Sempervivum* or Houseleek, some of the *Sedums*, or Stone-crops, and others of the same family, can produce a most grotesque effect. The hardy species of these plants, and there

adopt such changes, and are apt to continue to call a plant by the name they first knew for it. Until there can be a better agreement between botanists and florists, and other cultivators, we must submit to the inconvenience of having one set of names for botanical works, and another for the garden and garden works. To come to the plant in question, and as we speak of it as a garden plant, we give it its garden name, *Umbilicus sempervivum*, comes from the Eastern Caucasus. It makes

it was found that Lilies had long been favorites with the Japanese gardeners, who by careful hybridizing and crossing had produced garden forms of great beauty. In looking for the causes for the advance in Lily-culture, the efforts of our own cultivators in crossing and hybridizing must not be omitted; the splendid results obtained by Hovey, Wilder, Parkmann, Hanson, and others, as well as those by European cultivators, show what a promising field is still open to the patient florist. The

THE HOUSELEEK (*Umbilicus sempervivum*).

KRAMER'S LILY (*Lilium Krameri*).

are a great many of them, when once planted require but little care. They are scarcely affected by drouth, and when once well established, they take such full possession of the ground, and cover it so closely, that little else can get a foothold. The *Sempervivums* present a general resemblance in form, to that of a rosette, but vary in size, the shape of the individual leaves, and especially in color. Some bloom quite freely, but their flowers are generally of a dull pink or pale purple, and are not especially showy. Knowing this to be the general character of the flowers, we were surprised to see on a rock-work devoted to such plants in the grounds of Messrs. Woolson & Co., a patch of bright crimson, or almost scarlet. An examination showed that the plant was not a true *Sempervivum*, but a hardy near relative, of which we had seen accounts in European journals, a species of what the European Catalogues call *Umbilicus*, or Navel-wort. This one, from its close resemblance to the Houseleeks, is called *U. sempervivum*, the "Houseleek Navel-wort."

Modern botanists do not recognize the genus *Umbilicus*, but unite that and *Echeveria*, with *Cotyledon*. This is not the place to discuss such matters, and we can not explain further than to say that the best botanists find that the plants originally called *Echeveria* and *Umbilicus* are so much like those called *Cotyledon*, that they see no good reason for three different names, and they place them all under the oldest name, *Cotyledon*. Florists are generally slow to

small rosettes of very pale leaves, not much over an inch across. The second year they throw up the flower stem, when the plant appears as in the engraving, which is of the natural size. There are several other species, some of which have white, and others yellow flowers; the present species especially interests us as giving a positive and rich color among plants, which, though striking in foliage, are not usually very brilliant in their flowers.

### Some Notes on Lily Culture—Kramer's Lily.

One need not be very old to recollect the time when the old White Lily, the Tiger Lily, and the Martagon or "Turk's Cap," were all the lilies to be seen in ordinary gardens. Now the species and varieties are so numerous that it would require a large bed to contain but a single specimen or two of each. While in purity of its whiteness, in fragrance, and the grace of its typical lily form, the old white lily has not been, to our notion, surpassed, entirely new types have been introduced, and we now have a great variety in form and a wonderful range of color, including some of the most brilliant and some of the most delicate tints known among flowers. The great improvement in Lily-culture during the last 30 years or so is due to several causes, prominent among which is the opening of Japan to commerce. Not only were the native species of Japan introduced into our gardens, but

introduction into cultivation of our native species from both sides of the continent, has added new forms and color; indeed, those who have not made the experiment have no idea of the great variety in form and, within a certain range, of color, the common species of our swamps can present when transferred, as they well deserve to be, to the more favorable conditions of the garden. As with other plants, new introductions among lilies are for a while costly, but the majority, including the most beautiful, are sold so low as to place them within reach of all who can buy flowers at all. Their moderate cost is due to the fact that most of the species can be readily multiplied from the bulb-scales. Each of the scales of which the bulb is composed, will, under favorable conditions, form a bulb, and sometimes two or more. This method, now no longer a florist's secret, will allow any one to multiply these beautiful plants, as it requires not so much skill as patience. One has only to carefully pull off the scales, and a few of the outer ones can be taken without injury to the bulb, set them out, just covering them in boxes of light sandy earth, and keep them at a uniform temperature of about 50° or 60°. The earth is to be kept barely moist, not wet, and in about six or eight weeks minute bulbs will be formed at the base of each scale. All the lilies, except perhaps a few from the mountains of India, are hardy, and many that were formerly considered tender are now

known to have suffered, not from cold, but from a long continued high temperature. Some of our cultivators, following the English method, planted the tall-growing kinds, such as *L. auratum*, in their beds of rhododendrons. This was done for effect, merely, as it gave the lily-flowers the rich dark-green of the rhododendrons as a background the better to show off their colors, and it added to the attractiveness of the rhododendron plantations by clothing them a second time with flowers, as the lilies do not bloom until long after the shrubs have finished their display. Some of our friends who planted their lily-bulbs in this manner found a marked improvement; the flowers showing an increase in size and numbers. One who had never been able to get but one bloom from *L. auratum* when in an ordinary border, the bulbs either breaking up into numerous small ones, or dying out altogether, a trouble ascribed to the severity of the winter, accidentally left out the bulbs that were among the shrubs, and instead of losing them, as he expected, found the second summer's bloom much finer than the first. These experiences in different localities led to the discovery that our failure to secure results with lilies at all approaching those of the English gardeners, who make nothing of 50 or more flowers on the stem of a *L. auratum*, was not due to our more severe winters, but to the long continued heat of summer. The shade of the rhododendrons kept the soil cool and moist, and gave the bulbs just the most favorable conditions for their growth. Planting the tall lilies among deciduous shrubs can be practised by those who have no rhododendron beds. Where the lilies are grown in open beds, we have no doubt a light mulch, preferably of leaves, would be of great benefit to all the species. Among the lilies that flowered very satisfactorily with us this season is one known as Kramer's Lily, *Lilium Krameri*. This is of special interest, as it is supposed to be one of the hybrids of the Japanese gardeners, and it is thought that *L. longiflorum* and *L. auratum* are its parents. This, which the engraving shows of about half the real size, has the general habit of *L. longiflorum*, but is of a delicate rose-color within, and has a fragrance similar to, but less oppressive, than that of *L. auratum*, and is one of the best of its class.

### The Lubber Grasshopper.

A tin box came by mail with no mark as to its contents, and no letter referring to it, had been received. In such cases great caution is required in opening the package, as one has to be prepared for whatever may present itself. Slowly raising the cover there appeared the drollest, most knowing looking face!—much too small for that of a quadruped, and it seemed too large for that of an insect. Further examination showed it to be an insect—and a good deal of an insect when we consider that there were three inches of it! A letter received the next day from L. Phelps, Orange Co., Florida, explained that he had sent a troublesome grasshopper to find out what it was. Having the good fortune to possess a set of Prof. Townsend Glover's beautiful illustrations of the *Orthoptera*, we found that he had given the portrait of the insect and we here reproduce it. The engraving is rather below the size of our largest specimen, the body of which measured quite 3 inches in length, while its "hoppers," as boys call the hind legs, are at least  $3\frac{1}{4}$  inches long. The body, legs, and head, are yellowish, barred and spotted with black; the wing covers, which are thought by many to be the wings, in addition to yellow and black, have a handsome shading of rose-color. The portrait, in profile, fails to show the full face, which had such an intelligent expression that it did not seem altogether right to drown the creature in alcohol in order to preserve it. The eggs are laid in the ground, and the larvæ, as is the case with other grasshoppers, are much like the perfect insect in shape and movements, but are without wings, and are black with orange-red markings. Though the perfect insect has wings they are too small to be of use; it can not fly, and as it is very sluggish in crawling and clumsy in jumping, it has received the name of "Lubber Grasshopper." Its

scientific name is *Romalea microptera*—the Small-winged Romalea. The "Lubber" feeds upon foliage of various kinds, but shows a preference for the leaves of the Orange-tree, as Mr. P. writes: "especially the tender ones, and the buds that I have put in, and are my pride." The insects have long been known along the Gulf Coast, as far west as Louisiana, as destructive to garden vegetables of various kinds, and they are said also to eat the fruit of the peach and fig. However moderate their other movements, they are not slow in eating, and in all stages of their existence devour orange leaves most voraciously. As they are obliged to

THE LUBBER GRASSHOPPER (*Romalea microptera*).

crawl up the trees, it would not be difficult to arrange some barrier to their ascent. They are quite too much for domestic fowls, which refuse them. Being, even when young, slow to get out of the way, they are readily crushed under foot or caught in a net. As their destructive powers increase with their growth, they should be proceeded against when quite young; when they first make their appearance they are less than an inch long, and being so much blacker than the mature insect, may not be recognized as the same. They might be readily disposed of by the use of Paris Green or London Purple upon their food. We would suggest as more economical than poisoning the trees, to place leafy branches of the wild orange, or those that can be spared from cultivated trees, in pails or other vessels of water, to keep them fresh, and apply the poison to the leaves of these. The lazy insects would no doubt gather on these traps, as they would be saved the trouble of climbing for food.

### Fruit Dryers and Fruit Drying.

The great superiority of fruit dried by artificial heat, over that prepared in the sun, has turned the attention of many to the subject. So superior is the artificially dried fruit that in the market it bears as a trade name "Evaporated Fruit," to distinguish it from the common article, while the price at which it sells is so much higher that it may properly excite the interest of fruit growers. In October last we gave an account of the "Zimmerman," one of the modern dryers and our experience with it, but there are many who wish to operate upon a larger scale than is possible with a portable dryer, and several of these have written asking us to give a plan for constructing a large dryer. While we would willingly aid our correspondents, we are here met at the outset by the fact, that the various Dryers and Evaporators, large and small, are patented, and it would hardly be possible for us to suggest a contrivance for drying without unconsciously interfering with some one of half a dozen patents—especially as we do not know what each claims as his particular invention. Any fruit dryer must consist of a source of heat, and something to hold the fruit while it is drying. The mere drying of fruit by artificial heat, we suppose, cannot be patented; could it be, every woman who dries her sweet corn and pumpkin in the stove oven, with the door open, would be an infringer. Any improved or original methods of constructing these essential parts, is very properly patentable, and whoever would put up an apparatus for drying,

must avoid interference with these patents. Some patents are trivial, they do not cover inventions, but are for things that have long been in common use, and never should have been granted; and notwithstanding that such patents exist they are nuisances. We believe in patents, and are sure that our patent system, imperfect as it is, and as strangely administered as it sometimes seems to be, has vastly promoted the prosperity of the country. If there is any feature about it that we do not like, so long as it is the law, all good citizens will observe it. While we would do all in our power to aid one in resisting a false claim in regard to a patent, we

would not knowingly aid one in interfering with a regularly secured patent, however absurd the granting of it may seem. So in the matter of fruit dryers, while we would gladly aid those who wish to do so, to construct them, we should do wrong were we to give a plan that trespassed upon the rights of others. The best we can do is

to describe an unpatented arrangement, which includes all the essentials of a successful dryer. The first device for artificial drying we ever examined, was used in the preparation of vegetables in immense quantities for the army during the war. Enclosures or rooms of convenient size were made of frame work, and the sides covered with cotton cloth. The diagram giving an end section of one of these drying rooms will show the arrangement. At *a, a*, are steam pipes, the source of heat; these ran around three sides of the enclosure, near the bottom; slats *b, b*, were fastened across at intervals, to hold the trays, *c, c*, which were simple frames with a bottom of mosquito netting or other open fabric. The frames were alternately close against the side of the enclosure so that the hot air would take the course shown by the arrows. The cabbages, carrots, etc., sliced thin, and spread on the trays, were rapidly and perfectly dried. The whole was a temporary arrangement, put up in some vacant loft, but the product could not have been better had the most expensive apparatus been employed. This illustrates the general principle upon which all dryers are constructed; there is a source of heat in the steam pipes, and trays to hold the fruit or whatever is to be dried, and an arrangement by which the hot air is caused to circulate

DIAGRAM OF DRYING ROOM.

among the trays in the most complete manner. There was of course an opening for letting in an abundant supply of fresh air below, and another for the exit of the hot and moist air above. Whatever else there may be about a dryer, these conditions must be met. This description of an unpatented arrangement may be of service to those who wish to experiment in the matter. If a stove is used to supply the heat, of course a room inclosed by cotton cloth is out of the question. A word of caution is necessary here: wood work of any kind long exposed to a temperature much below that at which it is charred, becomes after a while exceedingly combustible, and will take fire with the greatest ease. Hence danger from fire is always present

and is to be guarded against. In some of the large patented dryers the trays are suspended upon endless chains, which pass over wheels above and below; the trays of fresh fruit are put in nearest the furnace and gradually raised as others are ready to go in below them. Those who propose to dry fruit on a large scale will very likely find it cheaper in the end to arrange for the construction of one that has been thoroughly tested, even though it is patented. The sum paid the patentee for the right to construct, according to his plans, may easily be less than an inexperienced person would expend in experiments and alterations, and after all, he runs the risk of making use of some device that has been patented, and may at the end have to pay more for it than it would have cost at first. It would be well for all who propose to dry fruit largely to look into the capacity of the largest Zimmerman, as well as examine the stationary apparatus.

### The Tortoise Beetles.

Mr. P. Frenzeny, Bergen Co., N. J., recently left with us specimens of an insect found upon his potato vines. Since the advent of the *Doryphora*, which is by common consent known as the Potato Bug, we hear much less than formerly of the dozen

Fig. 1.

other insects, known to live upon the potato plant. The insect left by Mr. Frenzeny, is one of the Tortoise Beetles, and though recognized as an enemy to the potato, has never been sufficiently numerous to cause much injury. As a representative of a group of insects, some of which are quite destructive of other plants, especially the Sweet Potato, and the larvæ of which have some marked peculiarities, we reproduce its portrait from Prof. Riley's Second Report on the Insects of Missouri, and some figures of the larvæ of related species. The insect is known as the Clubbed Tortoise Beetle, *Deloyala clavata*. The engraving is almost twice the real size. The broad, yellowish, transparent wing-covers, extend for some distance on each side, and at the rear, beyond the body of the insect, and in front there is a similar helmet-like projection beyond the head. The resemblance to a tortoise is still further increased by the dark opaque markings, which, extending to the edges of the shell, look much like the paws of a turtle. At the time this Report was made, the larvæ of this particular species was not known, it being the perfect insect that feeds upon the potato. But there are several other Tortoise Beetles, belonging to the closely related genus *Cassida*, of which the history is well known, and it is likely that the larvæ of this one, will be found to have similar habits. Fig. 2 shows the larvæ of one of these, the Mottled Tortoise Beetle, a well known enemy to the Sweet Potato in the Southern States. This has a forked tail, and uses it to spread a sort of screen or parasol, apparently to protect it from the sun. This shield consists of the dried dung of the insect, often mixed with its

Fig. 2.

Fig. 3.

cast off skins. In some, this parasol is irregularly three-lobed in shape, but in this it is in broad masses with branches, as in fig. 3, which shows a similar larvæ as looked down upon. As the excrement is thoroughly dry, there is nothing offensive about it, and its real nature might not be suspected at first sight. In marked contrast with what we can not help regarding as an unpleasant habit of its larvæ, is the great beauty of the perfect insect of one of the species, the Golden Tortoise Beetle, which Riley describes as "one of the most beautiful objects that can be imagined. It exactly resembles a piece of golden tinsel."

These species of *Cassida* are found on the wild Morning Glory, and also on the Sweet Potato vine.

### Teosinte for Warm Climates.

BY PROF. ASA GRAY.

When the *American Agriculturist* first figured and brought to notice the gigantic grass known as Teosinte, as a forage plant, it was careful to state that it required so long a season that it promised to be of value only in the Southern States. As we have been the means of sending seeds to subscribers in several of the warmer states, this spring, we hope to have reports of its behavior this fall. Prof. Asa Gray has gleaned some items as to its value in other countries which have an interest here. He writes:

The Director of the Botanic Garden and Government Plantations at Adelaide, S. Australia, reports favorably of this strong-growing, corn-like forage plant, the *Euchlena luxurians*; that the prevailing dryness did not injure the plants, which preserved their healthy green, while the blades of the other grasses suffered materially. The habit of throwing out young shoots is remarkable, 60 or 80 rising to a height of 5 or 6 feet. Farther north, at Palmerston, in the course of 5 or 6 months, the plants reached the height of 12 to 14 feet, and the stems on one plant numbered 56. The plants, after mowing down, grew again several feet in a few days. The cattle delight in it in a fresh state; also when dry. Undoubtedly there is not a more prolific forage-plant known; but, as it is essentially tropical in its habits, this luxuriant growth is found only in tropical and subtropical climates. The chief drawback to its culture with us will be that the ripening of the seed-crop will be problematical, as early frosts will kill the plant. To make the Teosinte a most useful plant in Texas and along our whole south-western border, the one thing needful is to develop early-flowering varieties, so as to get seed before frost. And this could be done without doubt, if some one in Southern Texas or Florida would set about it. What it has taken ages to do in the case of Indian corn, in an unconscious way, might be mainly done in a human lifetime by rightly-directed care and vigorous selection. Who is the man who is going to make millions of blades of grass grow where none of any account ever grew before?

### Melilots as Weeds.

It now and then happens that a plant heretofore regarded as harmless, finds a locality specially favorable to its development, becomes aggressive, growing where it is not wanted and is recognized as a weed. Singularly enough two species of the same genus, *Melilotus*, have come to us this year from widely separated localities—Maryland and Texas—to ascertain their names, and both represented as unwelcome intruders. There are two species of Melilot common in the older States, a white and a yellow flowered. Both are coarse branching plants 2 to 4 feet high, or even taller. The leaves are shaped like those of clover, rather smaller, and the divisions toothed; the flowers, which are minute pea-shaped are in little racemes, which go on lengthening and blooming, so that while there are buds and flowers above, the little one- or two-seeded pods at the bottom of the cluster will be full grown if not ripe. The engraving of the top of a branch of about the natural size will allow it to be identified if met with. The White Melilot, *M. albus*, is the one-figured, and the one brought from Maryland; the yellow, (*M. officinalis*) besides the different color of its flowers, has somewhat differently shaped leaves, there are other species, and all have the peculiar odor that is so marked in the Sweet-scented Vernal-grass, the Seneca grass, and especially the Tongue Bean. The White Melilot, known as Sweet Clover, and sometimes as Bokara Clover, is sometimes cultivated by those who are fond of its perfume. It was formerly cultivated in England, not so much as a fodder crop, as cattle will not eat it when fresh, but to mix with poor hay in order to perfume it. In Europe this or a related species is bruised and mixed with the curd to flavor it in making Gruyère cheese. This is

all that can be said in favor of the plant; it is often found as a straggler along road sides and in waste places, but not in a manner to arrest attention. Last June, Mr. T. Davids, who has a farm near Annapolis, Md., brought us a remarkably vigorous specimen, which reached as high as one's head, and branched from the very base. This, according to Mr. Davids, is spreading with great rapidity, making inroads upon the grass lands, appearing in the wheat fields, and threatens to be a serious pest. In case of the Texan plant, a specimen was sent by a correspondent of a plant that had suddenly ap-

THE SWEET CLOVER (*Melilotus albus*).

Single Flower and Pod Enlarged.

peared in his "bottom lands," as the alluvial banks of rivers are called in all the Western States, the term being the equivalent of *intervale* as used in New England. The plant proved to be still another species, the Small-flowered Melilot, *Melilotus parviflora*, of Continental Europe, and no doubt introduced by the early Spanish settlers, as it extends from Louisiana and Texas across through Mexico to California. We have seen it occupying acres along rivers to the exclusion of everything else, but even hungry mules would not eat it. It is not so robust a plant as the White Melilot, and has still smaller yellow flowers. These plants are troublesome as is any other that occupies land needed by cultivated crops. If left alone they are biennials, the root dying at the end of the second year, and after it has provided for its abundant increase by seed. If the tops are cut away before the seeds are ripe, we are met by another difficulty—cutting off the top prolongs the life of the root. Were a crop of seeds perfected this would so exhaust the root that it would die, but by preventing this we keep the old root which becomes stronger and pushes up its shoots year after year. There seems to be one of two alternatives: to grub up the root and make an end of it, or to cut frequently and continuously; as often as there is a sufficient growth for the scythe to take hold of, it should be cut away. The difficulty attending the destruction of this and many other weeds when well established, shows how important it is for the farmer to be able to recognize these plants in their young state. At that time a stroke of the hoe will, without difficulty, destroy a pest which, when it gets full possession, may require the work of hours to remove it.

**Currants** are one of the welcome small fruits in mid-summer, being especially welcome in the hot days. If left to themselves the season is short, but by covering the ground around the bushes with a heavy mulch, a screen of cloth, or even of newspapers, the season may be prolonged by several weeks.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### An Embroidery Frame.

For large pieces of embroidery-work, a frame that will hold the work up in front of the worker is not only a great convenience, but almost essential. The engraving here given shows such a frame, which is cheap and easily made. It consists of two standards, or legs, with curved cross-pieces at their bottoms to give it a firm footing, and two horizontal bars to hold the standards together, as shown in the engraving. The frame, made of four wooden strips, is held to the standards by two wooden pins passing through the tops of the standards and the middle part of the ends of the frame. By this arrangement the frame can be swung around with ease and the work placed at any convenient angle.

A SELF-SUPPORTING EMBROIDERY FRAME.

To those accustomed to use the simple lap frame, or any other, it is not necessary to state that it is best to stitch a strip of strong linen, or tape, along the woof ends of the material, which must then be sewed firmly to the webbing on the frame. All this work of putting the foundation on the frame should be done before that is adjusted to the standards; this latter can be easily done by pushing the pins into the places made to receive them in the frame.

### Home Topics.

BY FAITH ROCHESTER.

#### Care of Children's Teeth.

A mother of several children lately told me some of her experience. A few years ago she thought that her oldest boy's teeth in the front of the lower jaw were decaying badly. This was a disappointment to the mother, who had fed her children carefully on nourishing and wholesome food, as a general rule, keeping both pickles and confectionery from them. Studying the matter over, she jumped to the conclusion that what she had read concerning the mischief-making properties of the tomato must be true, especially as her husband, who was very free in his use of tomatoes in their season, had a peculiar trouble with his teeth. She had observed that the children's (especially the boy's) teeth grew white and clean when there was a plenty of ripe tomatoes, and she thought the acid of the vegetable probably went too far and acted upon the enamel of the teeth. But when the boy, then fourteen years old, went to a dentist to have his teeth filled, lo! there was no filling to be done. "Your boy has a splendid set of teeth," the dentist told the mother. "There is not a cavity in them. Unusually good teeth for a boy of his age." And the dentist had no doubt that the teeth were better than they would have been if the owner of them had munched candy and pickles, as children usually do. "They must be cleaned, and that without delay," he said. So the tartar which had gathered and crusted gradually at the crown of the teeth was removed by the dentist, and with it all appearance of decayed teeth. Now the boy has nothing to do but to keep his teeth clean in order to avoid dentistry hills in future. The younger children are warned to avoid the older brother's trouble by the daily use of tooth brushes. From their father's

case they learn to avoid the opposite extreme. His teeth are hopelessly discolored, and a few are habitually loose, but the useful tomato is no longer suspected as the cause. He had an opportunity to read some in a work on Dentistry, and came to the conclusion that hard "scouring" of his teeth with gritty substances, when he was a young man, had worn away the hard enamel of his teeth so that the strong coffee he drank (during his soldier life especially) penetrated and permanently colored his teeth. I dislike to hear of scouring the teeth. When they have been neglected this may be necessary to get them once clean. The dentist has peculiar tools for removing tartar crust, but the yellow deposit on children's teeth can be cleaned away as the dentist does it, by any one. Take finely powdered pumice stone and a little clean soft pine stick to rub with. Dip the pine stick into water and then in the powdered pumice, and rub the teeth gently. Afterwards wash them with soap and water, using a tooth brush. It is well to use a little fine clean soap occasionally for cleaning the teeth; but plenty of pure water (a little warm in cold weather) will usually suffice for cleansing the teeth of persons of good dietetic habits. To make good teeth in the first place, beginning when we can begin, and allowing for "ancestry," the mother should eat plain and nutritious food, a varied diet well supplied with bone material, as the grains are when it is not bolted or sifted out, and lean meat. For young children milk should be freely used, and graham and oatmeal also. [We are glad that so sensible and practical a person as Faith Rochester, hits this tomato nonsense on the head. Some two years ago a paragraph appeared somewhere to the effect that much of the trouble with teeth was due to the free use of tomatoes. This was copied in all the papers, and thousands of persons gave up the use of tomatoes to save their teeth. We at once stamped this notion as nonsense, and are glad to have our denial of the injurious effects of tomatoes, made on general principles, supported by what comes very near being direct evidence.—Ed.]

#### Clean Floors.

I admired my neighbor's bare floors until I found how they were made so spotlessly clean. "With soap and sand and a scrubbing brush," she told me.—"Applied by a woman down on her knees?" I asked.—"Yes," she replied. "You can have your's look like mine if you use the same means,"

No, thank you. Neither I nor my daughter shall put ourselves to this drudgery, and I shall not require it of any woman. Physicians say that the position assumed in order to scrub a floor with a brush and cloth makes the labor so done a positive injury to the woman, often resulting in very bad cases of female disease among working women. If floors must be scrubbed with soap and sand, a long handled brush or a broom should be used for the purpose. But all this hard scouring is unnecessary labor, if paint or oil be properly applied to the boards of the floor. Then only warm water or a weak suds is necessary for cleaning, and a nice long handled mop is the proper implement.

#### Starvation in the Midst of Plenty.

On the farm there ought to be plenty to eat for both man and beast. There is, usually, but they do not always get each a full share of nourishing food. The wheat alone contains all the elements necessary to maintain the growth and strength of the body. But when wheat is ground and bolted and made into ordinary fine flour, it is deprived of much of its most strength-giving properties. The fine flour is mostly starch, and starch alone can never make a very good "staff of life" to lean upon for strength. If the bran can only be made reasonably fine, it is better in our bread than out of it; but there is a great deal of graham (in western groceries at least) so full of coarse scales of bran that it is unfit for daily food, unless it is sifted through a common sieve. The portion of the wheat next the bran and mostly removed by the miller's bolting, is the most nourishing part of the wheat. To take this from the wheat and give it to the cattle is to starve our children in favor of the cattle.

What are the other staples of the farmer's hill of

fare? Potatoes and pork. Potatoes are good food in their kind and degree, but not alone. Like most vegetables they furnish some of the mineral elements needed in the animal system, but they are mostly starch and water. They should only be used to help make a pleasant variety, and not, as is too often the case, as the main dependence. Children are sometimes half-starved on them, though they appear fat and so are considered healthy. Starch belongs to the carbonaceous foods, as do sugar and grease. All of these help to produce fat, but afford little strength. So the "fine, healthy-looking child," as ignorant people describe the big-cheeked, fat baby, may be tired and feverish, craving it knows not what, and an easy prey to disease, for lack of good nourishment. Potatoes for children should be well mashed and dressed with good milk, instead of butter and fat meat. Potatoes and beef go well together, each furnishing something that the other lacks.

Concerning pork I have little to say. We never use it in our family. Those who raise their own, may feel so sure of its healthiness as to eat it without misgiving, but I wonder how any one who depends upon the common market supply can relish pork. It is always poor food for children, or for any one inclined to be bilious, and especially bad for those who are at all tainted with scrofula.

#### Variety in the Daily Food.

Though good wheat, or good beef, or good milk, may each furnish a perfect food, or contain all of the elements needed to support life, it is not best to depend upon any one article of food alone, except in the case of nursing babes, and then the mother should have a suitable variety. To obtain a variety, some house-keepers only go a round of different kinds of pie and cake, all equally bad perhaps; thinking that if the pantry is well supplied with these things, little other cooking is necessary. It is a great mistake. Cake and pie do not supply much actual food, and the good material that is used in them is put into such shape that the stomach is wearied and worn-out by the effort to digest them. This accounts for much of the tiredness complained of by women and girls. They are half starved, because their food is poor. The use of much poor trash called "dainties" (I don't abuse these things because I dislike them; I have a "sweet tooth," and know my own weakness well enough to understand the weakness of others), spoils the appetite for substantial food. The stomach is feeble for lack of good material in the blood (made constantly of our food and air) to repair its waste, and it takes food unwillingly because it is tired with overwork—overwork upon the concentrated conglomerations of rich cake and pastry. An error easily fallen into in such a case is to give up one thing after another because it "hurts" us, until the stomach becomes so weak it can hardly bear anything. It is slow starvation. We must not only "cease to do evil;" but must also "learn to do well"—not only give up unwholesome food, but eat plenty of that which is wholesome.

The proper variety is one made up of fruits, vegetables, grain, and animal food, the latter consisting of healthy meat, eggs or milk in its various forms. With palatable graham or oatmeal preparations, especially where milk is freely used, meat is seldom craved or found to be necessary to high health and strength, but when starch, sugar, and fat preponderate, as in the common fare of white bread and butter, potatoes, cake, pie, and a little sauce—beef (especially steak) often seems an absolute necessity to one who has to put forth strength. Coffee can not possibly supply its place. It does not give strength, but only stimulates it, or calls it out, making one feel strong while under its influence. Nourishing foods really strengthen us.

You would hardly believe, until you try it, how heartily a plain and nourishing variety of food is enjoyed by those who live with reasonable simplicity. It is easier in every way. All feel much better and more good natured, with no unreasonable cravings for confectionery, pickles, or stimulants. It lightens the care of children wonderfully. It makes the cooking more simple and easy, and, last but not least, it saves the doctor's bills.

### A Canvas Chair.

While on a visit to some friends in the country, not long ago, we made the acquaintance of a chair which was so easy, cool, and altogether suited for summer use, that we give an engraving of it, for the benefit of other friends in the country. An explanation of its parts is scarcely necessary, as it can be easily understood from the figure. The legs cross as in a camp stool, two of them being long, and with the canvas, forming the high back to the chair. Two braces which are attached near the center of the back are joined by a cross-piece, which fits into notches seen at the rear, and by moving

AN EASY SUMMER CHAIR.

the braces up or down, the back may be brought nearly upright, or horizontal. When not in use, the chair may be folded up so that it will occupy but a small space. If the chair is patented, we failed to see the mark which the law directs shall be put on to indicate that such is the case.

### A Hammock for the Household.

Merely the sight of a hammock hung in a cool and shady place is refreshing; it appears so comfortable and inviting. A hammock is not a sign of indolence, as some who think that they have no time for rest, except in the night, may regard it; it is rather an index of good sense upon the part of the owner who is aware that in the busiest life there are minutes that can be best spent in comfortable repose. Even on the farm in mid-summer there are half hours and quarter hours at noonday, or in the evening after the heat and work of the day are over, when the rest which an easy fitting hammock affords is just so much clear gain. Nothing that will give rest to the weary body and at the same time divert the mind is out of place in the farmer's household. If there are children in the family, there is nothing that can give them more amusement and comfort than a hammock, and the guests, whether of an hour or a day, will not object to the pleasure which it affords. Hammocks are not expensive, at least they do not now cost the price that they once did, when they were imported and their use was less general. Two or three dollars will now buy a very serviceable plain one; those that are elaborately made of course costing much more. In hanging the hammock it should be placed in the shade, either between two trees upon a lawn or upon the piazza and hung by hooks or screw-eyes placed in the columns or posts. If more particularly for children it should be somewhat lower than usual. For grown persons the hook which supports the head end should be six feet high and that for the foot four feet; this will afford the most desirable position for the occupant. The body of the hammock should be nearer the higher hook than it is to the other, and this may be secured by using a shorter piece of rope on the head end. There has been introduced recently a hammock hung to a portable frame; this frame folds up and occupies but very little space when not in use.

Of course, like most good things, the hammock may be abused—the comfortable rest which it gives may induce persons to remain too late out-of-doors, thus exposing them to the chilly or damp air of the night, but this is not the fault of the hammock,

and no argument against its more general introduction as one of the wholesome comforts of the farmer's home during the hot months of summer.

### Tents and Canopies for the Lawn.

To get out-of-doors in the hot days of summer is a common impulse. Even though the thermometer may show no marked difference in the temperature, the freedom of the open air is preferable to the confinement of the house. But to be out-of-doors one must also be in the shade. The natural shade of trees is pleasant occasionally, but rarely so desirable, take it altogether, as that of a tent. Trees are not always just where we wish the shade; the ground beneath them is often damp; and besides there are falling leaves, unwelcome insects, and other discomforts that make the tent preferable for a prolonged out-door sojourn. A tent may be made an important "annex" to the house in summer, and afford not only a pleasant place for reading, sewing, etc., but we have known it to do good service as the tea-room of the family during the hot days. The readiness with which children take to a tent as a play-ground is a sufficient evidence of its utility, were there no other. The simplest form of tent is a mere roof, without side walls, technically known as a "fly"—and this is in many cases all that is desired. Such a canopy is easily made and inexpensive. The materials out of which it may be made are various; common sheeting, heavy drilling, or duck, may be used; it will be found the cheapest in the end to get good substantial material that will last and look well for a number of seasons. The size of the canopy being decided upon, and the requisite material procured, all the making required will be to sew the breadths together and to make a broad hem at each end, with eyelet holes at each corner, and as many along the sides as there are to be ropes. If the material is heavy duck, the work must be done by a sail-maker, or by one who can use a sail-needle and "palm." Two upright poles, about 8 feet long, will be needed, and a light ridge-pole which will be as long as the width of the fly. An iron pin should be inserted in one end of each pole; this should be

Fig. 2.—AN OPEN TENT.

long enough to pass through a hole in the ridge-pole, and it will be all the better if it pass through the ridge-pole and project a short distance to allow an eyelet in the middle of the edge of the canvas to go over it. This is not always done, but will add much to the firmness of the "structure." Guy-lines or ropes, for holding the canopy in its position, must be provided. These are secured to the edges or "caves" by passing through an eyelet hole and making a knot in the end. Tent pins will be needed, as many as there are ropes; these are strips of hard-wood, pointed, for driving into the ground, and with a notch near the upper end for holding the guy-lines. For convenient tightening and loosening the ropes, it is well to provide each with a "beckct," which is piece of hard-wood, about 4 inches

Fig. 1. long and an inch wide, with a hole in each end, as in figure 1. The end of the guy-rope is put through the holes and a knot made.

The open tent is now ready to pitch, and when in position is as shown in figure 2. In this form of tent the ends are entirely open, but end pieces may be added with but very little trouble and ex-

pense, and the tent is much more complete. After the pitch of the main part has been decided upon, the cloth for the ends is cut, so that it will fit upon the open end, as shown in figure 3. This piece may be kept separate and adjusted by lace strings passing through eyelets, or sewn fast, as desired. The pitch of the end piece should be the same as that

Fig. 3.—OPEN TENT WITH ENDS.

of the sides, and the bottom should come in the same plane. A single rope and pin will be needed to keep the ends in place. Those who prefer greater seclusion in their lawn tent, will find it in

Fig. 4.—A WALL TENT.

the Wall Tent, shown in figure 4. They can be made of any size; and if of heavy material, can be used for "camping out." A wall tent complete has over it a fly, made just like the canopy first described. This makes the tent much cooler, and in heavy rains breaks the force of the storm and prevents leaking. A small Palmetto Tent, more especially adapted for children, is shown in figure 5, the construction of which can be easily seen from the engraving. The cost of it is small, in comparison with the amount of pleasure it can give the little ones, where they may "keep house all to themselves." If the tent is to remain for some weeks, it will add greatly to the comfort of those who use it to have it furnished with a floor. If the needed sills or sleepers and boards are cut the right length and put together with screws instead of nails, the floor will last for several years. In the suggestions for making a tent we have had shade and shelter only in view, but either style is capable of ornamentation; alternate strips of blue and white or red and white may be used, and the edges can be finished

Fig. 5.—SMALL PALMETTO TENT.

by a scalloped border, as indicated in figure 5. Besides small flags may be successfully introduced.

## BOYS &amp; GIRLS' COLUMNS.

## The Doctor's Talks.

This month we will change our "Talks" somewhat, and instead of the mechanical forces of nature, have something to say about a living object. I do not know how many have written me, first and last, about the curious object generally known as

## THE HORSE-HAIR SNAKE,

and the questions have not only come from youngsters, but from older persons. There is often to be found in shallow pools of water, and sometimes in horse troughs, a very long, slender object, curiously coiled and twisted upon itself, which has a very sluggish movement, but still enough to show that it is alive. The engraving, of the natural size, shows the so-called "Snake" to be a worm scarcely larger than a horse-hair, and about a foot long; being of small size, and frequently appearing in horse-troughs, many have supposed that it came from a horse-hair. Many people really believe that the hair from a horse's tail, after long soaking in water, can somehow "turn into" a snake. Indeed, I have known a person to keep a horse-hair in a bottle of water, expecting that it would

## TURN INTO A SNAKE.

Many of the letters about it ask if the thing really comes from a hair, showing how widespread is this belief. Others simply ask what it is. Now this creature no more comes from a horse-hair than does a mud-turtle from a hoot-jack. It is a creature by itself, small, it is true, but is as distinct as any other and much larger animal. Naturalists have not yet quite learned all about this Hair Snake, but so far as known, its history, rightly looked at, is quite as curious as if the creature really did come from a hair. The creature is not in any sense a snake, but is a worm. Its scientific name is *Gordius aquaticus*; the first name having reference to the "Gordian Knot," the animal having a way of twisting itself up almost inextricably; its specific name, *aquaticus*, was given because it is always found in the water, there being several other species which are not aquatic. These worms lay their eggs, which are hatched, and the young Gordiuses, in some manner, find their way into the bodies of Grasshoppers, Crickets, Locusts, and Water Beetles, being probably taken in with their food. Inside of these insects, like tape worms in large animals, they live and grow, and when they have reached their full

THE HORSE-HAIR SNAKE.

size, after having lived upon the food which these insects have taken for themselves, they at length leave the host that has entertained them so long, and are fortunate if they make their escape near water, where they can live for a while and lay their eggs for a new crop. A friend who gives much attention to the study of insects, informs me that he has often seen these "Hair Snakes" coming from the bodies of crickets, and can confirm the observations of European naturalists.

That one animal can live within the body of another may be new to you. Such animals are called *Entozoa*, a word from the Greek, meaning *within an animal*. There is a very large class of creatures that thus pass the whole or a part of their lives, it may be within the stomach and intestines of another animal, or it may be in some other part, the liver, the brain, and various other organs, affording a home for these creatures. That an animal like the Hair Worm should live within the body of a Grasshopper or Cricket, is indeed very strange, but it is something more than strange, such knowledge is useful.

## OUR DOMESTIC ANIMALS ARE TROUBLED

by various creatures that live within them. The Hair Worm, it is said, does not injure the Grasshopper, though it would not be of much consequence if it did, but with our domestic animals, while some of the Entozoa cause little or no trouble, others, when in great numbers, make

them ill, and even kill them. You will find on page 308 an account of the Fluke; the creature that causes in sheep the fatal disease known as "Rot." I think that all of you who are old enough to read about this *Gordius*, will understand that story of the Fluke. This creature, the Fluke, is said to belong to a very low order of animals, as its "make-up" is very simple. If it is simple in itself, it makes two different animals, two that are much higher in the scale, serve as its nurses. Early in the life of the Fluke, a little snail takes care of it, but it soon wants better food than the snail can furnish. The snail in search of food crawls upon the grass in a wet place; a sheep in search of food eats the grass, and without intending it, takes the snail also. The snail of course dies, but the little Fluke has found just the place it wanted—if such creatures have wants—and it goes on and causes all the trouble described in the article upon Sheep Rot. There are other Entozoa which have even more strange ways of living; and I may describe some of them another time, but what I wish to point out to you is this:

## SUCH STUDIES ARE USEFUL.

Useful not only because they show some of the wonders of animal life, and increase our knowledge, but have a real money usefulness. The naturalist who discovered that the young Fluke had the little snail for a nurse, added many hundreds of thousands of dollars to the wealth of farmers. He pointed out how the Fluke found its way into the sheep. No Snails, no Fluke, no wet pasture, no snails, and the preventive of the disease, is to keep sheep away from wet pastures. What a trifle it seems, to look at it in one light, but how important if we look at its usefulness to every farmer who keeps sheep! You may think I have wandered some distance, in going from Hair Worms to Flukes, but though they look so unlike, they are closely related; both are worms; both are Entozoa, or dwellers within other animals. I must tell you one more curious thing about the Gordius or Hair Worm. When the pool in which it happens to be dries up,

## THE WORM DOES NOT DIE,

but, as we may say, goes to sleep, and waits until water comes again. How long it can wait, I do not know, but an Italian naturalist put one away in a drawer, where it was forgotten for three years, and when at the end of that time it was placed in water, it became as lively as ever.

## My (The Doctor's Correspondence)

has not appeared for a few months, for the reason that most of the questions were answered in one way or another in other parts of the paper. It often happens that a boy or a girl asks about something which is very much like what an older person has asked about. For example, here is "J. H. N." in Nebraska, who would like to know

## ABOUT CANARY, OR BIRD SEED,

what kind of a plant it grows upon, and if he could raise it himself, as it is sometimes very difficult to get where he lives. Now this is just such a question as an older person might ask, and when I know that such an inquiry has been answered in the other parts of the paper, I do not care to put another in your columns. But as to Canary seed, it is the seed of a grass which has a very close head, not long and slender like a head of Timothy, but short and egg-shaped. It is, like the birds which eat most of it, a native of the Canary Islands, but the supply for this country comes mostly from Southern Europe, and is grown more or less in Germany and England. There will be no difficulty in growing it, for the Canary-Grass makes itself quite at home in this country; where the litter from bird-cages is thrown out, the plants come up, and it is not at all rare to find them in waste places. You may sow it early in the spring, either broadcast or in drills a foot apart; cut it when the seeds begin to ripen. It is a food that all cage-birds like—at least all the singing birds.... But some questions are not so easily disposed of. Here is one who would like to know about

## THE MIDSUMMER NIGHT'S SONG.

That song or sound every one of you must have noticed. What a wonderful sound it is: The chirps, the hums, the buzzes of a myriad of crickets, locusts, and I do not know what other insects, all blending to make that sound, always to be heard on a warm summer's night. It is a peculiar dull roar, serving as the base to the tenor chirp of of some near-by cricket, or the monotonous song of Mrs. Katy-did. But I did not set out to write about the sound, but I was thinking how much pleasanter it was to listen to it than it is to go in-doors to write. I am very sure that with cool evenings my budget of letters will increase in size. Sometimes the parents send questions to "the Doctor," and now and then I answer in the Boys' and Girls' Columns questions not especially intended for me.

## A FOSSIL TOOTH,

came safely to our hands, and is not forgotten. I suppose it to be the tooth of some animal, the kind of which is no longer living, but though I have engravings of many such teeth, I find none quite like this. When I come across some geologist who studies such things, I will try to find out the name of the animal.

## Picture Puzzle.

This is a queer kind of picture. The ox has some trouble with its head, as if some one was holding it back to keep him from eating the food in the pan that is for the dog. It may be that there is some one between the

two animals, and is keeping them from quarrelling. Is it moonlight? It may be that the obscure light of evening makes it more difficult to see the whole of the picture. To many of our readers, and perhaps all, the "picture in the picture," may be as plain as day. We hope for no trouble in finding what is to be seen.

## Our Puzzle-Box.

## WORD-MAKING.

(For explanation, see similar puzzle in the April number.)

1. List of words: lion, double, rat, beast, elm, matter, to; letters to be added, R, D. (Find the word in the above list, to which the letters R, D, may be added, to form another word by transposition.)
2. List: house, residence, future, tavern, local, tip; letters, O, H.
3. List: actor, basket, bust, model, gull, rim, pen; letters, R, A.
4. List: boat, steam, trotter, agate, little, conrse, miser; letters, Y, N.
5. List: Traveller, forest, broom, dust, clean, billow; letters, C, I.

## CONCEALED QUOTATION.

(The original sentence may be found in Shakespeare's *Troilus and Cressida*.)

How did I remember? Well, I keep a diary, and there it says—"the thing was made with hard rope, and girdled with a band of Roman steel. In it he had Pygmalion's ivory woman, elegantly carved, besides a miscellaneous assortment of rings, hooks, instruments of torture and locks of human hair tied up with solferino ribbon."

## DEFINITION PUZZLES.

(In each of the following definitions you can pick out the letters needed to spell the word that is defined. Example—"One devoted to any service." Now for this you might think the word "servant" would answer, as you can find in the sentence the required letters; but "servant" is not so defined in the dictionary. The word is "votary.")

1. Odd and antique.
2. An instrument or vessel.
3. One suddenly raised to wealth or power.
4. Produce of vines, and the time of grape gathering.
5. A word having the same, or very nearly the same meaning as another.
6. Simple; an inhabitant of the country.
7. Adorned; beautiful.
8. Destruction.

## CHARADE.

My first is eaten, oft, with milk,  
'Tis deemed by many, good;  
And in my next the children meet  
To take their daily food.  
My whole is deemed a luxury  
By many an epicure,  
And yet it is a common thing,  
You've seen it I am sure.

## SCATTERED SQUARE.

(In the following verse, you will find in the first line the letters needed for the first word of the square, and, of course, the initials of the four words. In the second line of the verse may be found the letters for the second word of the square; in the third line, the third word; and in the fourth, the fourth. In the first line, for instance, you may find letters with which to make the words—heat, reap, pear, pier, race, ache, etc. And it may not be quite so easy to select the right one as you imagine.)

The peaches are ripe,  
And red on the trees;  
The flowers are perfumed  
And scented the breeze.

CROSS-WORD.

My first is in cleaver but not in knife,  
My next is in bagpipe but not in fife,  
My third is in pity but not in ruth,  
My fourth is in infant but not in youth,  
My fifth is in fragment but not in piece,  
My sixth is in poultry but not in geese,  
My seventh is in bolster but not in bed,  
My eighth is in yellow but not in red,  
My ninth is in stay but not in bide:  
My whole is nothing but empty pride. MAGGIE.

SUBTRACTIONS.

1. Take one from four and leave one.
2. Take two from five and leave one.
3. Take three from five and leave five.
4. Take two from three and leave five.
5. Take one from six and leave eight.
6. Take one from six and leave nine.

SQUARE WORD.

1. To desire.
  2. A gem.
  3. A household article.
  4. A girl's name.
- F. CLARK.

NUMERICAL ENIGMAS.

1. I am composed of 29 letters:  
My 5, 10, 20, 15, 25, 8, describes a wheel in motion.  
My 19, 13, 16, 22, 1, is an article of apparel.  
My 17, 18, 11, 6, 14, 3, 2, 7, means this or that.  
My 12, 28, 26, 20, 25, 21, is imaginative composition.  
My 23, 6, 9, 4, 7, is extreme.  
My 24, 17, 27, is heard of grasses and grain.  
My whole cautions us against false pretenses.
2. I am composed of 11 letters:  
My 3, 2, 10, 11, is much used by dressmakers.  
My 6, 2, 2, 4, is a corner.  
My 8, 5, 6, is a receptacle.  
My 7, 10, 9, 1, is surly.  
My whole is a bird.

G. W. EVANS.

POSITIVES AND COMPARATIVES.

- (Example.—Grain, an angle. Corn, corner.)
1. Goods found but not claimed; a thin cake.
  2. A violent motion; a country in Europe.
  3. What blasters do; to meddle.
  4. An article of food; a tool.
  5. To wait on; easily injured.
  6. A number; a general course.
  7. A coin; the middle.
  8. To clothe; a kitchen table.

ANAGRAMS.

1. Gift protégé.
2. B. Hunter.
3. Irene Post.
4. Rant scene.
5. Send rim.
6. Sent charm.
7. Drew, read.
8. Very idle.

CROSS-WORD.—Friendship.

ILLUSTRATED REBUS No. 477.—Small leaks sink great ships.

Among the Birds.

This morning early, in fact, before we were up, the birds were out and giving their free open air concert, to all who would listen. The thoughts that this mingled morning song of gladness brought to us, were various; but among others, this; that perhaps the boys and girls of our *American Agriculturist* family, would like to have a Bird Rebus; and so we have had the artist draw some birds in his peculiar way. It is our work to give a little description of each, and leave it for the young readers to make out the rest.

The first bird we will notice, is pretty generally distributed throughout the country, especially near large bodies of water. It prefers the quiet and solitude of the forest during the day, and is most easily found in early morning, standing motionless by the side of a pond, etc., watching patiently for a fish, which, when within reach, is caught in the long bill, with about the quickness of lightning. Its nests are made in high forks of trees in swamps, where it is difficult for naughty or other boys to get the eggs or young birds. It may be said that the bird is of a bluish color, and has very long legs.—No. 2 is one of the common smaller birds, with rather highly colored plumage, sly, cunning, and very restless; in fact, a noisy bird, and one not at all liked by other members of the feathered tribe. It is unsafe to always judge of an object entirely from external appearances—so

here the beautiful garb of this bird is not a correct index of the heart within. It is a robber of other birds' nests, sucking the eggs, and devouring the young, at the same time being attractive in form and coloring, and graceful in movement.—No. 3 is a game bird, and one that every hunter likes to find in abundance. When found in the deep forest, these large reddish-brown birds are very tame and unsuspicious, but in older parts of the country, they get very wild and sly, from frequent contact with the sportsman. The way a group of these birds will retreat and hide themselves when discovered, is quite surprising. The nest is built of brush and leaves, and upon the ground. On the wing this bird is very swift, and its flight is far from a silent one. Like little boys on campaign years, they do a considerable drumming.—No. 4 is one of the large birds of prey; that is, a bird which lives upon animals, and those often of considerable size. Stories are told of severe struggles between this bird and men, who are bold enough to go into the solitary mountain regions, where they abound. The head, neck, and front of the breast are bare of feathers, giving the great, ugly bird a savage and disagreeable appearance. No nests are made, but instead the two eggs, about four inches long, are laid upon the bare rock, with a few sticks around them.—No. 5 is a common bird in the United States; it builds its nest in holes, which it digs in sand banks, along the borders of streams. The hole is often 6 or 8 feet in length, and very crooked. Its food is mostly fish, which it obtains by diving. The note of this bird is loud and harsh, but when heard above the roar of the water-fall, is not disagreeable.—No. 6 inhabits the pine forests of the Northern and Middle States, and derives its food from the pine cones during the cold weather. The bill of this bird is peculiar, but so well adapted for its work, that nature in making it of an unusual form, knew well what she was about. During deep snows, they often gather around the hunters' and wood-choppers' cabins, in great numbers.—No. 7 raises its young in the neighborhood of fresh water lakes, in the interior of the United States, and is afterwards found along the sea coast in autumn. The nests are built in the tops of broken trees, out of danger from rising water, and egg-loving animals.—No. 8 includes a number

of birds under the same name. The one we have selected, is a common and well-known kind, which comes North, from its warm summer quarters in the South, near the first of April. About the middle of May a nest is built in a lilac bush under the window, or in some other handy bush or tree. The nest is constructed of fine twigs, grasses, etc., and neatly lined with horse hairs. It is in these little nests, that the mean cow-bird lays her great white egg, which is hatched out by the little foster mother, to the great discomfort of her own little ones.—No. 9 is noted for getting up early in the morning, and

SOME OLD BIRDS IN A NEW FORM.

does it by making circles in its flight, which grow larger and larger, as it gets higher and higher. All this time it is said to be singing a beautiful morning song. We say, "it is said," because this bird does not exist in America, but is famous in the countries of Europe. There is a kind in this country, that is frequently found in the meadows, but as far as we know, it has no enviable reputation for "going out to meet the sun,"—in fact, it is a low flyer, but pleasant in its singing.—No. 10, the last bird we will mention, is one noted for its great strength, it being a large "bird of prey." It is now seldom seen east of the Rocky Mountains, and is rare everywhere. This noble bird, over three feet in length, is remarkable for its long sustained flight, which it performs with the greatest ease and grace. It seems fitting that we should close our notice of the birds, with one which holds his high place, as the "King of Birds."

The Spring Beetle, or "Blacksmith."

A queer looking beetle came in a box by mail, which has been sent, as a great many other insects are, for a name and a description—that is, the sender wishes us to tell about it. This beetle is of a peculiar ashy-black color, with two large velvety spots on its back, which are mistaken for enormous eyes by those who do not observe that they are not in the head. The real eyes will be found in the head, and just back of the long feelers that are so finely jointed and look somewhat like a string of beads. If you happen to

catch one of these beetles, as you may at this time of year, and place it on its back, you will see some fun. After a short time with a clicking sound the beetle will throw itself into the air and come down on its feet, and start off as if nothing uncommon had happened.

No. 479. Illustrated Rebus.—A few words of wisdom worthy of study by both old and young.

### Harry and His Horse.

It is a little more natural for a farmer boy to want a horse than for him to want to wait until he is old enough to take care of it. I felt very big when I could be trusted with a horse out of sight of any other person, with my "red top" boots, and a real, live horse; but when I look back and think of it, I now see that the horse which I thought I must hold with all my might or he would run away, was a very old and gentle one that rather cared for me than I for him. He would not have run away for all the world—he had lived too long to see any fun in being fast, and to move at all was a matter of great exertion and self-sacrifice. When boys can not get hold of a real, live horse, they do the next best thing, which is, to have a wooden one. Of wooden horses there have been many sorts—perhaps more kinds than of real horses; but the ones that are the best, that is, nearest the child's heart, are those which he makes himself. The picture here given shows what a little friend of ours can do in the way of getting up a "play horse" that furnishes him a world of amusement for a time. It is a very crooked branch of a very crooked tree, with the limbs coming out from the body in such places that they really look like the legs of a horse—at least they are of the same number. As for the head, though a little slender perhaps, it is seen to be the head. Not so much can be said of the tail. Well! some horses are "bob tails," though they are not so common now as some years ago. Harry has evidently had great sport with his pony, and has just brought him in from a drive, and has hitched him to a post—it is not always safe to hitch them thus, as they may frighten other horses that do not easily recognize their wooden representatives as horses. It is well to throw a blanket over him, as he may be sweaty, and there may be a draft blowing that might bring on a hard cold. How intently the large, rather, queer-eyed animal is feeding from the great, banded mitten. The oats, it is hoped, will make "Charlie" more fleshy than at present—though he is doubtless a race horse, and can not be expected to carry much extra flesh. The only fault I can find with the care of the horse is the lack of care of the drum—it is feared that with one single well directed kick the music-box will come to an untimely end, and in this, the year for drums. Harry in his haste for his own dinner—but his riding has made him very hungry—has overlooked the drum, but it is hoped that when he returns for his afternoon ride he will find everything all right. How Harry would feel to find his horse gone—to find that the hitching-strap had been broken, and "Charlie" had left for parts unknown. With such a

upon a lifeless, and some may even say ugly, stick, is to be highly praised, it is but the youthful overflow of a regard for the feelings of others; and whatever will develop that manly trait, even if it is the feeding of make-believe oats to a make-believe horse, should be encouraged. The boy that takes the best care of the toy that he makes or has had given him, will make the kindest, best, and most humane of men. For my part I see a good side in

long way off.—As cats now are, if they do lie down together, you may be sure that the bird will be on the inside of the cat. The instinct of animals is very strong; that something which impels the lion to eat the deer, and the bear to find its living animal food, is by nature so strong that any thing like "Daniel in the lions' den" will always be a striking story to children, because it is so unnatural and uncommon. The picture, which is here

THE WOODEN HORSE AT DINNER.

Harry in his giving his horse a safe place and a good feed before he goes to his own dinner, in waiting for him. U. H.

### The Cat and the Birds.

Cats and dogs, it is generally said, do not get along well together, but I have seen them so thoughtful of each other's interests and feelings, that there seemed to be a sort of affection between them: as if Old Bruno loved Tabby, and Tabby loved Old Bruno. Such cases are rather rare, it is true, and when we do see them they give us much pleasure. But when it comes to cats and birds the feeling is somewhat different. The cat seems to feel that a bird is made to be caught and eaten, and on the other hand the bird acts as if it thought that to keep out

given, teaches a great deal, while it is at the same time pleasing and almost funny. Here is a table, partly shown, upon which a stand of stuffed birds has been left, we may suppose for a short time, with no one in the room—save the household cat. "Old Pussy," that at most times would not do the wrong thing—would not get at the cream or milk, etc., because her "bringing up" has taught her better things, sees these birds so plump and life-like within her reach. With the quiet and stealth of a tiger, she creeps upon her prey! What a meal of nice tender bird she thinks is in store for her, and with this one thought of securing it, we find her upon the table, and with the greatest caution approaches the game, step by step. But now her eyes show that she has some doubt, as she pauses and looks half intent, half deceived,

"OLD PUSSY" AND HOW SHE WAS "SOLD."

tight hitch, and such a good supply of food so close at hand, it may be expected that everything will be in order, while in waiting for the return of the young horseman. If the horse gets away under such circumstances, may it not be a sort of evidence that he has been led astray by some other boy perhaps? The care which a boy will thus bestow

of the reach of the cat is the safest thing to do if its life is valued. There have been cats that, by severe training, have been made to feel that a bird's life is not for her to take; but it is an unnatural state of the cat's mind, and not to be depended upon. The time may come when the cat and the bird will lie down together; but it seems a

upon the feathered creatures that are quite too tame for birds of flesh and blood. They do not flutter their open wings or move their little heads, but have their eyes fixed with a glassy stare upon the coming foe. Because we love the little harmless birds more than the larger cat, whose nature it is to catch them—and for which we can not blame her—we all enjoy the picture, and are apt to exult in the safety of the work of the bird-stuffers, and have but a grain of pity for "Pussy," who has had her practice in bird-catching for her pains. In the supposed cruelty of the cat we are apt to forget that the bird, when alive, did not hesitate to take the life of an insect, with just as much cruelty, and while the cat is catching one bird to satisfy its hunger, the bird is perhaps killing a hundred, or a thousand, insects, to preserve its life. But the cat must retire from her high place on the table, where she should not be, and that quickly too, when the owner returns, with the feeling that all things in this world are not what they at first seem.

UNCLE HAL.

## THE CHAMPION REAPERS & MOWERS.

The Acknowledged Monarchs of all Grass and Grain Cutting Machinery, And Fully Endorsed by Agricultural Mechanics as the Most Wonderful Machine Ever Invented.

Awarded the Highest Honors Everywhere.

The CHAMPION REAPERS and MOWERS will be on exhibition this fall at most of the County, District, and State Fairs, and Expositions throughout the United States and the British Provinces.

Every Inquiry promptly answered by addressing either of the following Manufacturers or Branch Houses:

WHITELEY, FASSLER & KELLEY, SPRINGFIELD, OHIO, 19 South Market St., Boston, Mass., or Schenectady, N. Y.; CHAMPION MOWING MACHINE CO., SPRINGFIELD and Cincinnati, Ohio, St. Louis, Mo., Omaha, Neb., St. Joseph, Mo.; WARDER, MITCHELL & CO., SPRINGFIELD, OHIO, and Chicago, Ill.; and the TORONTO REAPER AND MOWER CO., TORONTO, CANADA.

## Embossed Scrap Pictures.

Sample Packages of New Sheet for 25c., 50c., and \$1.00, sent by mail, Post-paid, on receipt of amount. Stamps taken.

OSCAR W. YOUNG, Importer,  
Box 2114, New York.

## PARENTS! REMEMBER THAT THE A.S.T.C. BEAUTIFUL BLACK TIP

UPON CHILDREN'S SHOES,  
Reduce Shoe-Bills More than One-Half,

AND ADD TO THE  
BEAUTY OF THE FINEST SHOE.

### AUTOMATIC Eye-Glass Holder.

Just the thing to save your glasses and make them handy! Pins right on your vest and stops just when you want it to. By mail, 25 cts. Circulars free. Agents wanted.

J. S. BIRCH & CO.,  
38 Dey St., N. Y.

## COLUMBIA BICYCLE.

Bicycle riding is unsurpassed as a method of travelling, whether for speed, sport, or the renewal of health. No horse can compare with the bicycle for endurance, no other pastime is half so fascinating, and the exercise is recommended by the medical profession as being most conducive to health. Apleyford rode 100 miles in 7 hours, over a common turnpike road, and Waller has accomplished 1,400 miles in 6 days. Send 3c. stamp for 24-page catalogue, containing price lists and full information, or 10c. for catalogue and copy of "The Bicycling World."

THE POPE MFG CO.,  
No. 101 Summer St.,  
Boston, Mass.

1880 Established 34 Years, 1880

Both designs on each label. Saleratus the same.

**NONE BETTER MADE! TRY IT!**  
Office, 11 Old Slip, New York. Factories, Harlem.

## NEEDLES

Male and Female Agents wanted to sell our FAMILY NEEDLE PACKAGE, containing 120 Large-eyed English Needles, as follows: Four papers, 25 in each, different sizes; also, two steel Bodkins, 3 Long Cotton Darners, 3 Short Cotton Darners, 2 extra fine Cotton Darners, 2 W. 1, 2 Yarn, 1 Worsted, 1 Motto, 2 Carpet, and 3 Shoe-Benton Needles.

We will send a Sample Paper to any one mentioning the American Agriculturist for a 3-cent stamp.

LONDON NEEDLE CO.,  
24 and 26 Fourth Avenue, New York.

**FOR SALE.**  
500,000 Transplanted CELERY PLANTS.  
Prices and Pamphlet on Celery free.  
J. A. DAVIS, Gardener, Allegheny, Penna.

## BERRIES.

QUEEN of the MARKET and CUTHBERT, the largest, WELSH, the earliest Red Raspberry, 10 Acres Strawberry, Mt. Vernon, Sharpless, Warren, Longfellow, Kiefer's Hybrid, Blight-Proof Pear, "40 Years' Experience in Pear Growing, telling how to avoid the Blight." "40 Years' Among Small Fruits, telling What and How to Plant." Either sent by mail for 5c.; both for 25 cts. Catalogues free.

WM. PARRY,  
Cinnaminson, N. J.

## STEVENS' PATENT Breech-Loading Sporting Rifles.

Double and Single Barrel Shot Guns, Pocket Rifles, Pocket Pistols, and the noted Hunter's Pet Rifles. Special attention is called to our Double Breech-Loading Guns. They are simple in construction and manufactured with great care from the very best material. They are pronounced by experts "the best gun in the market for the money." Our Shooting-Gallery Rifle is the Favorite everywhere. Send for Catalogue. J. STEVENS & CO., Chicopee Falls, Mass.

A book devoted entirely to PLYMOUTH ROCK fowls, also a separate book on each of the following breeds: LIGHT BRAHMAS, WHITE LECHORNS, and BROWN LECHORNS, and a book on curing POULTRY DISEASES. Either of the above mailed for 25 cts., or all five for \$1.00. Address the author H. H. STODDARD, Hartford, Ct.

## World's ONLY Manufacturer of WHEEL CHAIRS

Exclusively.—ALL Styles and Sizes for Invalids and Cripples

Self-propulsion by use of hands only, in street or house. Comfort, durability, and ease of movement unequalled. Patentee and Maker of the "Rolling Chairs" pushed about at the Centennial. For Illustrated Catalogue send stamp and mention American Agriculturist. HERBERT S. SMITH, 32 Platt St., New York.

## RUE'S PATENT POTATO DIGGER.

DIGS IRISH  
OR SWEET  
POTATOES

JONES' PAT.  
Polished Steel  
DRILL POINTS

Fit all drill bits, run level, on flat bottom furrows, cover with shallow soil, and instead of crowding the seed into narrow rows but one inch in width, scatter it 3, 4, and 5 inches; the plants thus standing wider apart, have more ROOM TO STRETCH, derive more nourishment from the soil, become more vigorous, and produce better developed average heads.

Send for Illustrated Circular with Testimonials to **J. A. JONES, Wilmington, Del.**

"I was in my brother Tom's wheat about a week ago, and I really believe there is one-third more wheat where it was drilled with your points. Tom told me he had measured some rows and found **sixty-three** heads in the same length of row, against **forty-two** of the old way of drilling."

**H. CLAYTON** (Pres. Citizens' Nat. Bank of Middletown, Del., and farmer). "I got five bushels to the acre more wheat where I drilled with your points than with the old style. I gave them a fair test, showing you no favor."

**JOSHUA CLAYTON, JR., Mt. Pleasant, Del.**

## "CREAM" OF THE STRAWBERRIES

For 1880,

are shown in our Colored Plate, illustrating the eight best sorts; which, together with our Method of Culture, (by which a **FULL CROP** can be obtained in **TEN MONTHS** from time of planting,) we will mail free to all who apply by letter.

**PETER HENDERSON & CO.,**

35 Cortlandt St., New York.

ALL THE CHOICE NEW SORTS.

## I. X. L. FEED MILL

All Iron but the Hopper.

Cheap, Effective,  
and Durable.

CAN BE RUN BY ANY  
POWER.

Capacity from 6 to 30 bushels per hour, according to size. Send for Catalogue and prices.

**U. S. WIND ENGINE & PUMP CO.,**  
Batavia, Kane Co., Ill.

## "ACME" PULVERIZING HARROW, CLOD CRUSHER, AND LEVELER.

### Has 12 Steel Coulter Teeth and 10 Steel Cutting Spurs.

Cuts over six feet wide and two to four inches deep. The only implement combining Pulverizer, Crusher, and Leveler; performs all three operations at one time and in the most perfect manner. Works perfectly on light soils, but

Is Especially Adapted to SOD and hard CLAY where other Harrows utterly fail.

NASH & BROTHER, Sole Manufacturers, 22 College Place, NEW YORK, and Harrisburg, Pa.

## Champion of the World! THE CHAMPION GRAIN DRILL

With or without Fertilizer, or Grass Seeder Attachments, or Gum Spring Hoes.

It has a perfect force feed Grain Distributor that will sow accurately all kinds of grain without the least injury to the seed. The most perfect Force Feed Grass Seed Distributors in the market. Fertilizer attachment can be relied upon to sow all kinds of commercial manures whether dry or damp in any desired quantity. Draft Light, Construction Simple, but durable. Liberal discount to cash customers. Send for descriptive circular.

JOHNSON, GERE & TRUMAN,  
Owego, Tioga Co., N. Y.

The Pitts Agricultural Works, Buffalo, N. Y., U. S. A.

## ORIGINAL AND ONLY GENUINE BUFFALO PITTS

THE STANDARD of Threshing-Machine excellence throughout the Grain-Growing World. SELDOM EQUALLED. Never excelled. NOTORIOUS as a just yet thorough threshing machine, perfect cleaner, and entire sower of all kinds and conditions of grains and flax and timothy seeds. NOTORIOUS as the only machine that is a success in all kinds of threshing and a failure in none. NOTORIOUS as the best built, most durable, and handsomest of the Threshing-Machine Tribe. STEAM THRESHERS a specialty. Their superiority, it can be said with truth, is acknowledged throughout the world.

**CAUTION** To Agents as well as Threshermen. Be sure you get the genuine Buffalo Pitts, made only at THE PITTS AGRICULTURAL WORKS, Buffalo, N. Y. It is said that other manufacturers are using the name "Buffalo Pitts" on their make of Threshing Machines. This Unintentional Compliment to the great reputation of the only genuine Buffalo Pitts, by use of its title to sell inferior machines, is flattery to the "Buffalo Pitts." But Agents and Threshermen must not be deceived, nor hold the genuine Buffalo Pitts responsible for the faults of its bastard namesake. For Catalogues and Price-Lists of the genuine Buffalo Pitts, address

THE PITTS AGRICULTURAL WORKS,  
Buffalo, N. Y., U. S. A.

## Union Railway Horse Power.

THRESHERS AND SEPARATORS. These Powers are GUARANTEED to produce more Power with

LESS ELEVATION than any other Railway Power. Send for descriptive catalogue. WM. L. BOYER & BRO., 2101 Germantown Ave., Phila., Pa.

Also, manufacturers of the PREMIUM FARM GRIST MILL.

## CHICAGO SCREW PULVERIZER.

Does Pulverization pay?

ABILENE, KANSAS, Nov. 10, 1879. I seeded 3,400 acres of wheat with these machines. The stand of wheat is now the best I have ever seen on new land. R. J. WEYMES, Trustee.

DANVILLE, ILL., Dec. 4, 1876. This year I harvested, on 190 acres, 6,100 bushels of wheat. In my opinion the Screw Pulverizer increased the crop one-third over what I could have got by any other method. D. G. MOORE.

Send for pamphlet with cuts, and over sixty letters from men who have the machine. Address,

Chicago Scraper & Ditcher Co.,  
34 METROPOLITAN BLOCK, CHICAGO, ILL.

## La Dows Jointed Pulverizing & Smoothing DISC HARROW.

Being jointed in the center, is adapted to both smooth and uneven surfaces. Acknowledged the best of the kind, and will pulverize and cover seed better in one operation, than going over twice with others. Made with both Chilled Metal and Cast Steel Discs polished. Send for circular and price list. Manufactured by

WHEELER & MELICK CO.,

Albany, N. Y., for the United States.

By EVERETT & SMALL, Boston, Mass., for the N. E. States, and by Budlong & Co., Aurora, Ill., for Ill., Iowa, Wis., Minn., Neb., Kan., and Mo.

## 1880.-LEVEL TREAD HORSE POWERS.

HEEBNER'S IMPROVED

Level Tread Railway Horse Power and Speed Regulator.

Heebner's Improved Little Giant Threshing Machines. Send for Illustrated Circulars to HEEBNER & SONS, Lansdale, Mont. Co., Pa.

Grind your bone meal, crush your own oyster shells in the \$4.00 Hand Mill. Larger sizes for farmers—to run by power. Testimonials furnished. FRANK WILSON, 52 Delaware St., Easton, Pa.

FARMS. 150 Delaware Fruit and Grain Farms cheap. Catalogues free. A. P. GRIFFITH, Smyrna, Del.

It is the best tool in the world for preparing land for winter grain, whether the grain is to be drilled in or broadcasted.

It is Highly Recommended by the Editor of the American Agriculturist. See March number, pages 84, 96 and 122.

Thousands in use—all giving the most perfect satisfaction.

Agents wanted. Send for circular.

## The IRON DUKE WIND MILL is the Best and Cheapest for the following reasons:

It is ALL IRON. Is Self-Regulating. Will pump with less wind than any mill ever made. Will not shrink, warp, split, decay, and will stand more work than any mill extant.

DON'T BUY till you have received our Circular.

O. S. GILBERT & CO.,  
Manufacturers, Indianapolis, Ind.

## HALLADAY STANDARD WIND MILL.

VICTORIOUS AT

Phila., 1876—Paris, 1878.  
25 Years in Use.

GUARANTEED SUPERIOR

To any other Windmill Made.

Winger's Improved \$20.00 double Feed Grinder, which is operated by Pump Wind Mills—a novel and perfect Mill for grinding all kinds of grain for stock and house use. Agents wanted everywhere. Send for catalogue B. Branch Factory at Kansas City, Mo.

E. B. WINGER,  
Successor to STOVER WIND ENGINE CO.,  
Freeport, Ill., U. S. A.

## Ne Plus Ultra Automatic Windmill.

New, ten foot diameter of wheel, one horse-power, elegant and durable, made expressly for raising water for Farm and House Uses. PRICE \$50.00.

Any person can set them up.  
KEWANEE MFG CO.,  
35 Broadway, N. Y.

# THE HOMESTEAD, A HIGH-GRADE SUPERPHOSPHATE.

As manufacturers of Animal Charcoal, we have at our hands the most valuable material used in making fertilizers—viz., Bone Black Dust. This fertilizing substance contains eighty per cent. of phosphate of lime, against fifty-five per cent. contained in raw bones; and its well known value commands so high a price in the European markets that but very few manufacturers of fertilizers in this country use it. Although the HOMESTEAD Fertilizer costs us more to manufacture than if prepared of the materials generally used, we shall continue its present high standard, and place on the market a genuine, pure Bone Black Phosphate.

MICHIGAN CARBON WORKS, DETROIT, MICH.:

Gentlemen:—Please notice the enclosed photograph of wheat cut from the same length of drill, seven inches apart—superphosphate and no superphosphate. Draw your own conclusions which is which. Of course, this is showing more difference than the field will average; but this shows what superphosphate will do on very poor soil. This was cut from a very poor spot, but each having the same chance, with the one exception. It was cut 12th of June. Shows the earliness of that fertilized. I have the best piece of barley in this section—100 lbs. superphosphate per acre sown on wheat stubble. The best farmers here are taking note of these things.

ALMONT, MICH., June 18th, 1879.

Very truly,

F. J. GROAT.

MEDINA, ORLEANS CO., N. Y., August 7th, 1879.

MICHIGAN CARBON WORKS:

Gentlemen:—Enclosed please find a photograph of some barley. This barley was grown on A. H. Poler's farm, four miles south of Medina, Orleans Co., N. Y.

I made a frame four feet square and set it in the standing grain on the day of its being cut. I then cut and gathered all that stood within the frame of each, where there was phosphate and where there was no phosphate. I let it lay in the sun one day to cure, then weighed each bundle as you see it on the photograph.

The phosphate was put down with the seed with a fertilizing drill, the teeth being six inches apart. These bundles were cut side by side, only six inches apart. The one on the left of the photograph had no phosphate, and weighed twelve ounces. The one on the right had one hundred and forty pounds of the Homestead Superphosphate to the acre, and weighed two pounds and fourteen ounces to the four feet square. This is correct.

A. H. Poler also experimented on corn, potatoes, and winter wheat, with as good results on each as on his barley. Of course he has not harvested his corn; but it stands sixteen inches higher than the rest of the corn and earing one-half better.

Yours, respectfully,

GEO. W. POLER.

## ACTUAL RESULT AT OUR SEED-FARM ON LETTUCE SEED.

Homestead produced.....	583 lbs. per acre.	116 lbs. of lettuce seed, at \$1.25.....	\$145 00
Where none was used.....	467 " "	560 lbs. of Homestead, at \$40 per ton.....	11 20
Difference favor of Homestead.....	116 " "	Actual profit per acre.....	\$133 80

Send for Circulars, giving full reports of results and all particulars in regard to use.

## I. X. L. SPRING TUG LINK

Patented Feb. 24, 1880.  
Affords the greatest protection to **HORSES**, Harness, Wagons, Plows, Mowers and Reapers. Reliable and guaranteed as represented. Protect your Horse, save your money, by procuring the celebrated **D. RISHER & CO'S I. X. L. Spring Tug Link**. Ask your hardware man for them, or send to  
**D. RISHER & CO.**  
Corner of 4th and Wood Streets, Pittsburgh, Pa.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 300.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the American Agriculturist are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the American Agriculturist (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Grain Drills.**—The even sowing of the grain at the desired depth, the proper covering of every grain, and therefore a saving in seed, are some of the important points in favor of using grain drills. Within a few years a new value has attached to these implements: the grain is sown in rows, and thus allows of the use of a cultivator, or Wheat Hoe. The importance of stirring the soil between the rows of wheat is now becoming well understood; and the practice of hoeing wheat is on the increase. In Sept. last we illustrated a home-made wheat hoe, and there are some implements for the purpose now offered by their makers. With the more general use of the wheat hoe the method of broadcast sowing must pass away. Except on new land, where the stumps are thick, there is nothing in favor of the broadcast sowing.

**Soil and Dry Weather.**—"Heavy crops succeed a season of drouth." There are good reasons for the truthfulness of the above remark. In the first place, a wet season, especially one with heavy drenching rains, causes the soluble food materials to be carried down deep into the soil, or even out of reach of the plants, if the subsoil is very porous. On the other hand, during a drouth, a reverse action takes place; then, as the surface moisture is evaporated the loss is made good from below; the water in the soil is brought up by capillary attraction, and with it the salts of potash and other fertilizing materials are carried up towards the surface of the soil and left there as the water is evaporated. It is upon this principle that the alkali covering on the western plains is produced. During a drouth the vegetation is not vigorous, and but a small crop is removed from the soil; the soil during dry weather is, so to speak, having a holiday—a sort of half-way summer fallow—in which food elements are forming in the soil, and not being used up by the plants because it is too dry for them to do much at growing. With such a preparation it is natural that the crop the next season should be a good one, provided there is rain enough for the sown plants to grow.

## Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending July 10th, 1880, and for the corresponding period last year:

An active and generally buoyant Stock Market; growing in money; depression in Foreign Exchange; and extraordinarily free movements in the Produce line have been the prominent features of the past month.

General merchandise has not been in much request, and has been irregular as to values, though the changes have not been very important. Comparatively little interest has been shown in Cotton, especially on speculative account, and the fluctuations in price have been within narrow limits. Wool has been attracting more attention, opening the month at easier figures, but leaving off more firmly. The more urgent offerings of Foreign formed a leading influence in causing the early depression. It has been noted that the fall in value of the past few months is most noticeable in the medium and low grades, and is especially evident in the decline on Super Pulled Wools, which, during the activity of the late Winter, reached a point higher in proportion than any other class. Good Supers, which in February commanded 62c. @ 65c., can now be bought for 42c. @ 45c., a shrinkage of over 30 per cent. Petroleum has been advanced sharply, closing buoyantly, on reduced offerings in the seaboard markets, and a more urgent inquiry from the export interest. Naval Stores varied little, on a slow trade. In the Provision line, Hog products have been quoted decidedly higher, and active; partly due to speculative influences; but largely to the extraordinary export drain, particularly for British and Continental markets. Beef irregular, and slow of sale. Butter has been recently in fair demand, at hardening rates. Cheese fell very materially in price, early in the month, under a pressure to realize, but has since rallied about 1 1/2 @ 2c. Hops have been quoted lower, as the available supplies have been more liberal, and holders more eager to place them, leading to increased activity. Unusual animation has been reported in the way of Breadstuffs, here, as well as at the interior, on more or less excited and disturbed markets; the tendency, early in the month, having been, as a rule, decidedly downward; while within a week or two, Wheat has rallied sharply, as influenced, mainly, by the reports from the West, of very unfavorable weather and resulting damage to the maturing crops. The heavy rains also were represented as causing much delay and trouble in preparing the harvested grain for market. On Friday, July 9th, business in Winter Wheat here was characterized by remarkable excitement and buoyancy, notably No. 2 Red, on which a further and very marked advance was made, especially on early deliveries, which, on very meagre offerings, were run up 5c. @ 7c. a bushel, as against operators having contracts to provide for, calling for deliveries within the first half of the current month; and options, in sympathy, gained about 2c. @ 3c. a bushel. Settlements to a limited extent of early deliveries were forced at the extreme figures. Subsequently, values weakened perceptibly, but the market closed more firmly. Spring Wheat has been recently in very good request, for shipment, at rising prices. The foreign market advices have been more encouraging to the export interest. Corn fluctuated here considerably, closing heavily, on, however, an active movement. More inquiry has been reported for Oats, which, however, closed at reduced figures. Rye attracted increased attention, almost wholly for forward delivery, prime Western leaving off for August delivery at 74c. @ 77c. and September at 76c. @ 77c. Flour has been more freely dealt in, opening weaker, but closing more firmly. The visible supplies of Wheat—embracing the boards at lake ports, in transit, and on the seaboard—at latest dates, embraced about 12,265,000 bushels, of Corn, 16,733,000 bushels; of Rye, 211,350 bushels; of Barley, 236,000 bushels, and of Oats, 2,824,000 bushels, against on January 31, an aggregate of 30,100,000 bushels Wheat, 13,100,000 bushels Corn, 979,000 bushels Rye, 4,155,000 bushels Barley, and 3,080,000 bushels Oats. Ocean Grain freights have been decidedly brisk—largely in the chartering line, and on speculative account, at advanced rates, closing firmly, including by steam to Liverpool, 6 @ 6 1/2, per bushel; to Bristol, by steam, to 9d. per bushel; to Antwerp, by steam, to 8 @ 8 1/2, per bushel, and sail to Cork, for orders for vessels of average carrying capacity—say 3,000 to 4,000 qrs.—5c. 6d. per qr. of 480 lbs.

General merchandise has not been in much request, and has been irregular as to values, though the changes have not been very important. Comparatively little interest has been shown in Cotton, especially on speculative account, and the fluctuations in price have been within narrow limits. Average per Week	15,414	80	5,264	34,766	27,096
do. do. last Month	15,430	37	6,275	35,650	31,571
do. do. prev. Month	13,485	69	4,700	26,505	36,585

Prices for hives the past four weeks were as follows:

WEEK ENDING	Range.	Larger Sales.	Aver.
June 11	8 1/2 @ 10 1/2 c.	9 1/2 @ 10 1/2 c.	9 1/2 c.
June 21	8 1/2 @ 10 1/2 c.	9 @ 9 1/2 c.	9 1/2 c.
June 28	7 @ 10 1/2 c.	9 @ 9 1/2 c.	9 1/2 c.
July 5	6 @ 10 1/2 c.	9 @ 9 1/2 c.	9 1/2 c.

Bees.—The receipts have not varied much from the average for the four weeks. There was an uncommonly active market during the second week, with good prices. The Texans and Cherokees, the first of the season, came in during the third week. These steers sold

at 7 @ 7 1/2 c. to dress 55 lbs.; Colorados to dress 56 lbs., sold at 9 @ 9 1/2 c. The range for native steers was from 8 1/2 c. to dress 56 lbs., to 10 1/2 c. to dress 57 lbs. Milk Cows.—There is a dull market for these now. Prices range from \$25 to \$55 per head; but for an extra milk cow for family use, as high as \$60 to \$65 is sometimes given. Calves.—All grades of calves have had quick sales and good prices. Buttermilk calves were firm, and sold at 2 1/2 @ 3 c. for ordinary to extra, and Veals at 4 @ 6 c. for common to choice. Sheep and Lambs.—Prime sheep were in demand and sold readily. Lambs were also in request, and the month closed with a firm market. Sheep sold at 3 1/2 @ 5 c. for poor to choice; Southern and Western lambs at 5 1/2 @ 6 c.; those from New Jersey and Pennsylvania at 6 1/2 @ 7 c. Hogs.—There are no live hogs for sale. The market quoted nominally at 4 @ 5 c.

The Horse Market.—There has been some demand for light carriage horses that would sell for \$300 to \$350. Heavy draught horses have been wanted, and brought a good price. There has not been much doing in the other grades; in fact, the horse market is dull.

## Farming with Irrigation.

It is a common idea that those who can irrigate their land are independent of changes of the weather and other natural influences. While irrigation allows lands to be tilled, which, without it, are valueless, and greatly increases the yield, and consequently the value of most arable land, it does not place the farmer quite beyond the reach of all untoward influences. The following note from G. Thompson for the past four years the Water Master for the District, which includes Richmond, Utah, is of interest. He writes: "The Water Master in this district is appointed by the City Authorities, and gives bonds in \$600 for the faithful performance of his duties. He has all control of waters leading from the mountains in the district of four miles square; to assess and collect taxes for the repair of water courses and ditches, and the distribution of waters during the season. We have 2,500 acres of farming land, and 350 city lots. The amount of taxes per year on farm land is \$500, and on city lots \$360. The Water Master receives a remuneration of five lbs. of wheat to the acre, and 25 cts. to the city lot. We water the farm land on an average of twice each season. City lots, for vegetables and trees, have water once per week. Last season the grasshoppers ate two-thirds of our grain crops, and most of the grass from the stock range, so it was very hard on our stock last winter. We had to commence feeding on the first of November. Therefore straw stacks, straw sheds, and every eatable thing had to go to keep our animals alive. I

**Veterinary Education.**—Every now and then we are asked if one can not qualify himself to be a Veterinary Surgeon by studying by himself, and are asked what books should be used. We would gladly aid and encourage self-instruction in every case where it is proper. The present improved condition of veterinary medicine is due to the fact that the Veterinary Surgeon of the present day is no longer a conceited but ignorant "horse doctor," but a man who has qualified himself for his profession, and is as well educated as the regular M. D. We do not propose to aid in lowering this standard by the encouragement of any half-way qualification, and one can no more properly fit himself by his unaided studies to practice upon beings with four legs than he can to doctor those with two legs. In both cases the very foundation of a proper education is a thorough grounding in anatomy and physiology; these can only be properly learned by the aid of dissection under a competent demonstrator; this, if nothing else, would prevent one from educating himself, and there are other equally strong reasons against its practicability. The fact is, that no profession holds out greater inducements in the promise of a successful and profitable career, than that of Veterinary Surgeon. But it only offers this to those properly qualified. While it no doubt seems otherwise to the applicants, we are really doing them a kindness when we advise them to not add to the number of half-educated quacks who call themselves Veterinary Surgeons. Those who intend to be properly educated can do much in the way of preparation by a study of text books in the various departments of instruction. The list is too long to be given here, but those interested in the matter will find it in the catalogue of the American Veterinary College, which may be obtained by addressing Prof. A. Liantard, Dean of the Faculty at the College; No. 141 West 54th St., New York City.

**"Some" Experience with Rabbits.**—One of our editorial staff, had a bright lad of 11 years, who had the rabbit fever quite bad. He produced figures to show that he could pay all his own expenses if he could get the "plant." So, after considerable investigation in the market, the father took home a fine pair of lop-ears, at a cost of \$25, and ordered an improved "Hutch" constructed at a cost of \$16. While waiting for this, the rabbits were kept in two large dry-goods boxes made of inch pine boards. The young "proprietor" went early every morning to count up the expected progeny, and had as much figuring on the results as the milkmaid had on her eggs. But one morning's observation showed by the teeth marks, that some strong animal had gnawed and wrenched off the inch-thick boards and the scattered fur and bits of skin were all that remained of the splendid dam. The "state of mind" of the "proprietor" was not to be described. —MORAL: Ask the Boy for it. P. S.—Thinking that the marauder, whatever it might be, would be meat-hungry again, and try the buck, a liberal amount of beef was placed near the box. This was gone the next morning. A few rods off was a monster dog, of the "female persuasion," which had evidently laid down to rest, and forgot to wake up at daylight. Some may suppose that the Arsenic bottle got overturned accidentally on that meat. But there wasn't any arsenic on the place, either in any of Prof. Dana's crystals, or in any other form. We haven't said anything about s-t-r-y-c-h-n-i-n-e.

**About Lightning Rods.**—The lightning rod vendors have established such a bad reputation that the people in all parts of the country are shy of them. If there are any who deserve to be trusted it is their misfortune to be engaged in a business in which there is such a number who are to be avoided. In cities there are persons in the business of erecting lightning rods who thoroughly understand it, and who have established a reputation for good work and fair dealing. Those who live beyond the reach of competent parties, and who wish to protect their buildings are at a loss how to accomplish it. Our advice is often asked in such cases, and this is intended as a reply to a number of inquiries. There is nothing about the proper erection of a lightning rod that may not be done by any intelligent person, aided, it may be, in some parts, by a blacksmith. The rules to be observed are not many, but they must be intelligently complied with, else the work had better not be undertaken. An imperfect rod is vastly more unsafe than none at all. If one starts without a pretty thorough familiarity with the laws of electricity, he needs much fuller instructions than can well be given in such an article as we could find room for in our pages. Fortunately there are excellent little hand-books in which the subject is treated in all necessary detail; one of these is by Prof. John Pluin, and there is another, the name of the author of which is not just now at hand. Taking a work of this kind as a guide, one should carefully study it in advance of beginning the work, in order that the principles involved may be well understood. While copper is a better conductor of electricity than iron, the greater cost causes iron to be generally used. A round iron rod  $\frac{7}{16}$  in diameter may

be used, but the use of square rods and of flat strips is becoming very common. A strip an inch wide and  $\frac{3}{16}$  of an inch thick is a good size, is easily applied, and when painted of the same color as the house is not generally noticeable. Contrary to former notions, the rod may be painted any desired color. Insulators of glass between the rod and the house are regarded as worse than useless; were they of use at any time, so soon as they become wet their insulating power is offset by the conducting power of the water. The termination of the rod in the air was formerly of platinum or of heavily gilded metal, and great care taken to have a sharp point. Now iron is used, and little attention given to sharpness. A rod projects a few feet above the chimney, and there are uprights often along the ridge. The proper termination in the ground is of much importance. The lower end should by all means reach permanently moist earth, and it is all the better if a rod can end in a well. Prof. Pluin's work may be had of the Orange Judd Co. Price by mail 50c.

**Dog Fennel Once More.**—Our friends in the Southern States are occasionally troubled by their cows giving bitter milk, and we have had a number of inquiries within the past few months as to a remedy. When the milk is bitter from anything that the cows have eaten, we doubt if anything can be done to remove the unpleasant taste. In such cases prevention is better than cure. Ascertain what causes the bitterness, and keep the animals from it. There appears to be some disagreement as to the plant which causes the trouble. A lady wrote from Texas that it was due to "Dog-Fennel," while Prof. Phares, of Miss., ascribes it to "Bitter-Weed." It is quite likely that both are right, as both are positively bitter herbs. Dog-Fennel is the common name for *Eupatorium foeniculaceum*, an own brother to the well known Boneset or Thoroughwort. Bitter-Weed belongs to the same family of plants, but to a very different genus, being *Helenium tenuifolium* and is a southern brother to our well-known Sneezewort. The statement by Prof. Phares, that cows will not eat Dog-Fennel (July, p. 285) is now contradicted by H. Woodbury, Morgan Co., Mo., who says that cows will eat this and various other weeds. He says that in his own State and in Arkansas, he has seen them leave a pailful of corn-meal slop and eat the Dog-Fennel, and suggests, as seems very probable, that they eat this and other bitter plants as a kind of tonic. Milk is too sensitive an article to tamper with, and no attempt to neutralize or overcome any unpleasant taste or odor, derived from the animal's food, is likely to succeed. The remedy must begin with the pasture.

**The American Institute** will hold its Semi-Centennial Exhibition, next year; this year its 49th exhibition will begin Sept. 15th, and last until Nov. 27th. It perhaps cannot be avoided, but these occasions are largely used by dealers to advertise their wares, and much that is shown can be seen in the shop windows. Still, in spite of this, there is always enough that is really new and useful to make the exhibition well worth attending, and the spacious building is sure to be well filled, at least every evening during the season. There has been in past years much concerning the management of the Institute that has been sharply criticised, but the present Board of Managers seem to be working to make the Institute as widely useful as possible. Among other indications of this is the encouragement this year offered to "Amateurs and Apprentices in all branches of Mechanical, Industrial and Decorative Art." It is proposed to admit "without charge, for exhibition and competition, all such work as may be approved, and to award premiums to those who may excel in the arts named." We understand that besides the regular trades and the acknowledged arts of Sculpture, Painting, Drawing, etc., this offer includes Faney Work, Embroidery, Decorated China, Wood Carving, Scroll Sawing, and all other artistic handiwork, calculated to adorn American Homes. Applications for space are to be made before Sept. 1st, to the General Superintendent, Room 23, Cooper Union, New York City.

**Turnip Greens.**—"A. W. K." Oldham Co., Ky., sends for trial the seeds of "Turnip Greens," which is the basis of the Kentucky dish known as "jowl and greens." The plant, according to our correspondent, is a variety of turnip which produces a large top and a small woody turnip, and in his climate is sufficiently hardy to generally grow all winter. The seed is sown at the same time as late turnips, and the greens may be had any time during the winter. He says:—"We commence eating greens after Jan. 1st, boiling them with a small piece of bacon, or in salt water, if preferred." He says the plant is liked by bee-keepers as a producer of pollen and honey.

**Silk Culture in Alabama.**—Samuel R. Lowery is President of an Industrial Academy at Huntsville, Alabama, where it is proposed to give colored youths of both sexes a thorough English education and instruct them in various Agricultural, Horticultural and Mechan-

ical pursuits. Prof. Lowery proposes the raising of silk upon a sufficiently large scale to test its value as affording an occupation, especially to females, being greatly encouraged by the experiments that have been made on a small scale by his family. Every endeavor by the colored people to help themselves, has our best wishes, and if this experiment helps establish the practicability of silk culture as an industry it will benefit the country at large.

**Facts About Florida.**—A correspondent who left Wisconsin on account of his health, and settled in Florida only after two years of wanderings and explorations, takes what we have no doubt is the correct view of the State as a place for settlers from the Northern States. He thinks that the State has been much overpraised by parties interested in the sale of lands. He says: "Many have come here who have failed elsewhere, and nine out of ten of these will fail here. There is an honest living here for those who will earn it, in the raising of about the only thing the country is fitted for—Oranges. I owe much to the country, but I would advise no one to own a grove unless he can come here to attend to it personally." And to this we would add, that it takes some years to get an orange orchard into profitable bearing. Of course one must have capital enough to start the trees, and either capital or other resources to subsist upon while caring for the trees and waiting for them to bear. These points should enter into one's calculations in advance. With a bearing orange grove, we presume, there are no doubt many attractions in the business, in the climate, etc., if one can locate so as to have desirable social and educational advantages for a young family, if he have one.

**Rye for Soiling.**—The first soiling crop in early spring is rye. For this purpose it should be sown late this month or early in September. A deep, mellow soil, well supplied with rich manure, is the one which gives the best returns for the trouble. After it is cut in the spring the rye will spring up again, and even a third crop may thus be obtained from the same sowing, and at intervals of a few weeks.

**Population of our Large Cities for 1880.**—The returns of the Census recently taken show the following population for the 17 cities of the United States having over 100,000 people. The population of the same cities for 1870 is also given, to show the growth that has taken place in the past ten years:

	1880.	1870.		1880.	1870.
New York...	1,207,000	952,000	Cleveland...	156,000	93,000
Philadelphia...	847,512	674,000	Pittsburg...	153,000	86,000
Brooklyn...	554,000	396,000	Buffalo...	150,000	117,000
Chicago...	474,000	299,000	Newark...	137,000	105,600
St. Louis...	400,000	310,000	Milwaukee...	130,000	71,000
Boston...	360,000	250,000	Louisville...	120,000	100,000
Baltimore...	350,000	267,000	Detroit...	119,000	79,000
Cincinnati...	250,000	216,000	Providence...	104,000	68,000
Washington...	160,000	110,000			

A number of changes in the scale has taken place. Chicago, that stood fifth in 1870, takes the fourth rank; in fact, changes places with St. Louis. The same with Boston and Baltimore.

**Riparian Rights.**—"D. K." Rhode Island. The term comes from the Latin *ripa*, a river bank, and in law refers to the privileges and rights of persons owning land along rivers and streams. It would take too much space for us to give even an outline of the subject, as there are the rights in common law and their modification by the laws of different States. A very good idea of the matter may be obtained by reading the article under the above heading in the 14th vol. of the American Cyclopædia.

**Points or Shoes to Wheat Drills.**—Whoever claims to increase the yield of wheat from the same amount of seed will be very sure to receive attention. The seed wheat, as it is put into the ground from the ordinary drill, lies in narrow strips about an inch wide. If the same amount of seed could be so placed as to occupy a strip three or four times as wide, it is evident that the plants will have more room, and that their early development, taking place without crowding, will be more vigorous, and the plant better prepared to give its yield of grain. J. A. Jones, Wilmington, Del., makes a Drill Point of his own invention, which may be attached to any drill in place of the points of the old style. These points are so constructed as to run steady and level, forming a flat-bottomed furrow from  $\frac{3}{4}$  to 5 inches wide, and to scatter the seed over the whole width. This is a matter deserving the attention of wheat growers.

**Overstocking the Farm.**—There is such a thing as keeping more than a profitable number of cows or sheep upon a farm. A half dozen half-starved cows will not yield as much milk as three that have all the food that they want. If there is no more stock than can be well kept the returns will be the greatest in money, and also in the satisfaction of seeing the animals in a good, healthy condition—no small part of the income to one who loves to have good stock well kept upon his farm.

### Quack Grass: How Subdue It.

"W. A.," Fort Atkinson, writes; "Will you kindly tell me whether there is any way of ridding a piece of land of Quack-Grass. I have a piece in corn this year, but cultivation only seems to spread it, and make it worse." This complaint is but one among many, and we make a general reply. The grass in question (*Triticum repens*), has a number of common names, among which are Quick-, Twitch-, Quack-, and Couch-Grass. If the grass has taken complete possession of the ground, forming a tough mass of "roots," there is only one way of ridding the soil of it. The ground should be plowed as deeply as possible in fall, so that most of the "roots" may be loosened, and turned up. Leave the land thus plowed until spring, then go over it with a cultivator every two weeks, until time to sow buckwheat. So soon as the buckwheat is harvested, begin cultivating again, not allowing the Quack-grass to make any start to grow. After cultivating each time in autumn, the ground should be raked to remove the "roots" of

and of preference through acquaintance with a particular pattern. With these, as with other farm implements, it is better, other things being equal, to purchase of the one made nearest home, or the most accessible, so that should a part be broken, or otherwise out of order, it can be replaced with the least possible delay.

**Pot-Grown Strawberry Plants.**—For the benefit of those who would establish a fruiting bed in the shortest possible time, and are willing to take the trouble, we described some twelve or fifteen years ago the method of layering strawberries in pots. This method has since been adopted by the nurserymen, and nearly every one who deals in strawberry plants at all offers those that are "pot-grown." As some of our correspondents do not seem to understand the matter, we explain. The strawberry plant is propagated by what are called "runners." A runner is a long very slender branch, with a bud at the end. Ordinarily this bud rests upon the surface of the bed and strikes root; the young plant grows rapidly, as it is supplied with nourishment from the mother plant, and soon is fed by its own roots, and when it becomes established, sends out runners of its own to form other plants. If the plants from the runners formed early in the season are left where they started, they would bear fruit next year, but we wish to make a new bed elsewhere, and the young plants are taken up either in the fall or next spring and planted out. Plants thus treated, having their roots disturbed, must grow a year in their new place before they are strong enough to give a good crop. It makes little difference whether we take up such plants and make a new bed in Sept. 1880, or in April, 1881, they will require all of 1881 to become sufficiently well established in their new bed, and strong enough to give a crop of fruit. They may, and often do, bear a few berries the first year, but not enough to be desired. If, instead of allowing them to take root in the bed, we place under the runner a small pot filled with rich soil,

HOME-MADE HORSE-RAKE FOR QUACK-GRASS.

the grass that have been loosened and left on the surface. A rake for this purpose is shown in the accompanying engraving. The head is made of a piece of hard wood, 4 inches square, and 5 feet long, in which a tongue is set and braced. A pair of old plow handles complete the wood work. The teeth, of iron, should be  $1\frac{1}{2}$ -inch wide, by  $\frac{1}{2}$  thick, made somewhat scythe-shaped, and provided with a shoulder brace, and nut and screw. The position they take in the head-piece is shown in the engraving. With this implement, the "roots" of the Quack-grass can be gathered rapidly into windrows, after which they can be raked into heaps, and carted off to a safe place, where they may dry and be burned or rot into manure. For a small patch, a potato hook will serve the same end, in removing the "roots" from the soil.

**Saving an Historic House.**—A pint or less of water applied at the right instant will stop a conflagration that a few minutes later can not be subdued by the most powerful steam fire engine. An illustration of this was afforded not long ago at the College of William and Mary, Williamsburg, Va. The President's house was erected in 1732, and being accidentally destroyed by the French troops in 1781, was rebuilt by Louis XVI. out of his own private funds. This dwelling accidentally caught fire on the roof from a burning chimney. The roof, being a French one, is very steep and difficult to reach, but fortunately one of the neighbors had one of Whitman's Fountain Pumps which enabled him to throw a small stream just where it was needed and the building was saved. In this case there was an abundance of water, and of assistants, but these were of less use in subduing the fire than a small quantity of water sent to the right spot by this excellent little hand engine.

**"Which is the Best Grain Drill?"**—A question like this, in regard to the various kinds of farm implements, is frequently asked us, and is very difficult to answer. In the present case, it is impossible for us to say which grain drill is the best. The agent for the "Farmer's Favorite" will claim that his is superior. The "Champion" men will bring up all the arguments in favor of their drill, and the "Hagerstown" and "New Gearless Buckeye" will have their advocate, while one who has used the "Victor" will be warm in its praises. The fact is that each one of the leading drills is so nearly perfect that it is a very difficult task to decide which is best, it being largely a matter of taste

and let it strike its roots in that, we have then what is called a "pot-grown" or "pot-layered" strawberry plant.

In practice these pots are filled with rich compost, and each one is sunk in the soil of the bed where it can be reached by the end of a runner; the runner is placed on the soil of the pot and held in place by means of a small clod or hooked stick until it strikes root. When the roots have filled the soil of the pot and need more room, the new plant is separated from the mother plant by cutting the runner, and the ball of earth is turned out of the pot and placed in a new bed, where, its roots not having been disturbed, it goes on and grows without any interruption. Plants so treated are in just the same condition with those that take root in the bed and left undisturbed, and will bear a good crop the next spring. The runners struck in pots in June and July, and planted out in August and September, 1880, will bear a fine crop in the summer of 1881. Of course such plants cost much more than those grown in the ordinary way, as the labor of producing them is considerable, but those who are in a hurry for fruit are usually willing to pay the extra price. A reference to our advertising columns will show that the leading dealers offer strawberry plants that are pot-grown.

**The Eucalyptus Tree.**—Notwithstanding that there are about 100 species of *Eucalyptus* recognized by botanists, one species, *Eucalyptus globulus*, the Australian Blue Gum, is generally spoken of as the Eucalyptus. This is due to the fact that it is more widely known than any other species, as it has been more generally planted outside of Australia than any other, as a rapid-growing timber tree. A few years ago it was claimed that this tree had the power to render malarious regions healthy, and much was said upon planting the Eucalyptus, in the daily papers as well as in the agricultural journals. The *American Agriculturist* stated at the beginning of this excitement that the tree would not be hardy in any of the Northern States, but papers which should have known better continued to set forth its alleged anti-malarial properties, and it was only after there had been many disappointing failures that the excitement subsided. We were surprised to find the subject revived, and the planting of Eucalyptus advocated anew by a journal so generally well advised in such matters as the *N. Y. Evening Post*, which, in an otherwise well-considered article on "Trees in the Streets," in its issue of July 10th, has the following:—"The Eucalyptus is said to be a safeguard against malaria; and in that

case parts of Manhattan which are notoriously infested by malarious disease might be fringed with this tree to infinite advantage." It might be of "infinite advantage" to fringe other "parts of Manhattan" with orange trees or with pine-apples, and either would succeed about as well as the Eucalyptus. It is a matter of regret that this subject has been revived, and that by a journal of influence. It should be generally understood that this Eucalyptus is barely hardy in Georgia, and that it will not succeed north of that State anywhere on the Atlantic slope. On the Pacific coast the conditions are favorable, and it has been extensively planted, and with remarkably successful results as to rapid growth. Whether there is any real foundation for the belief in its anti-malarial powers is doubtful. If the tree does prevent malaria, it is impossible for the people of Manhattan or other northern localities to avail themselves of its powers, as it will not survive a single winter in the open air. Indeed, the tree, so far as the climate of New York is concerned, cannot be regarded as half hardy. Having a tree in the grounds that had grown too large to return to the greenhouse on the approach of winter, we, by way of experiment, carefully protected it with a covering of straw. Though the following winter was a mild one, it was in spring found to be thoroughly dead, root and branch.

**Potato Bugs Valuable.**—It's just our luck! Yesterday we wished to try a new remedy, and found that there was not a bug on the potatoes, and we rejoiced. To-day we learn that potato bugs have a market value, and, of course, we have none! It must be true, for it is in print! A man in Queens Co., Md., tried burning his bugs, and didn't like it; then he tried boiling, and made the great discovery that the pot-liquor would dye leather and linen a brilliant crimson. More than that, the goods, after dyeing, were stronger than before. As we read these wonderful things, we thought we might raise some bugs, but some one has got ahead of us on that, and even the boys are engaged to pick 'em. There is a company that will go into the dyeing business. They have engaged 10,000 quarts of bugs at six cents per quart, and expect to want more. The bugs must be kept alive until the company is ready to begin operations—that is, they mustn't die until they are wanted to dye, and the company has erected a building in which to feed the bugs. The beauty of a hoax of this kind consists in keeping just within the limit of probability, but this is a very clumsy piece of humbuggery, quite overdoes it, and breaks down of its own weight.

**Altitudes.**—"J. S.," Salt Lake City, Utah—The barometer is used to take altitudes with the greatest accuracy, but as you only wish to do so approximately, you may find the boiling point of water to answer your purpose. It is a well-known fact that water boils at a lower temperature when the pressure of the atmosphere is diminished. Another fact is, that the higher the altitude the less the pressure of the atmosphere. As we ascend a mountain, water boils one degree lower for every 550 feet we go up. With an accurate thermometer and a contrivance for boiling water, you can come very near the altitude. We doubt if there is any satisfactory answer to your other question.

**Clean Fruit Baskets.**—J. R. Hawkins, Mountville, N. Y., thinking that many fruit cups and baskets are not improved for future use, by being taken to hospitals, and being kept for a while in sick rooms, and considering that these receptacles are rarely returned in a clean state, sends with his fruit a card insisting that the cups and baskets be sold with the fruit, and he will supply new ones with each shipment. The great trouble in this matter is, that people do not want the cups, etc. The majority of those who buy berries take a basket to market and have the contents of the small packages emptied into it. It seems a matter more easily arranged with the consignee or retailer than with the customer.

**A Farm Forge.**—A farm without an anvil, a vise, blacksmith's tools, etc., is not thoroughly equipped for its best and most economical work. To these tools there should be added one of the small forges that have been so much improved of late, and are now so perfect in their action and handy in the farmers' blacksmith shop. These forges are so cheap that they are within the reach of all, and, if proper use is made of them, will pay for themselves in a very short time. As the use of a forge means the presence of a fire, it is important that they be used with due caution.

**Grass Named.**—H. M. Charlevoix (no State)—The grass of which you wish the "name, history and use" is Orchard grass, *Dactylis glomerata*. If by its "history" you refer to its origin, we may say that it was introduced from Europe. Its use is as a meadow grass, it being by many preferred to Timothy, by itself or to sow with Clover. It should be sown very thickly, as otherwise it tends to form clumps or tussocks; thick seeding also makes the foliage finer. The seed is kept by seedsmen.

## "Just the Thing I Wanted,"

says a subscriber who has already received and thoroughly tested one of the new **Beach's Folding Fret Saws**. He says: "It does its work so well, is so handy to use, is so strong, stands so firmly, and then folds so quickly and so closely that it is out of the way in a minute. Then it is so cheap, and mine cost only 30 cents for bringing it 98 miles. I would not take \$10 for it if I could not get another. I want to thank the Editors of the *American Agriculturist* very much for taking hold of it, and bringing it before their readers. I hope every boy and man will have one."....This is talking pretty strongly, but not more so than the apparatus deserves. A good many others talk in the same way. In answer to letters of inquiry, we answer that it runs true and steady; that the table is tilted very easily by simply turning a screw, that is, the table holding the wood to be sawed can be inclined to one side or the other, so that the Saw will cut at any desired angle, for bevelling. The Saw cuts so smoothly that inlaid work is very beautifully made, even to very fine lines. The Saw is strained or kept tight by the simple action of the two arms. (See description and engraving on page 257, last month.) A great commendation is, that with all its advantages, the whole apparatus is supplied (cased for carriage) for the low price of \$2.25, and it folds so closely as to cost but little for carriage, and requires very little room for storage when not in use. Those who prefer to save the price (\$2.25), can obtain one as a *Premium* for sending four subscribers to the *American Agriculturist* at \$1.50 a year, or eight subscribers for half a year at 75 cts. Subscriptions can begin at any time—though it is preferable to begin July 1st or January 1st. We can always send back numbers from January 1st, 1880, or any desired numbers or volumes for twenty-three years past, as we keep electrotype plates for printing from. Old or new volumes or numbers are at the same price.

"**Little's Chemical Fluid**" is the name of a sheep dip that has been much used in England, and has found favor with those who have tried it in this country. It is free from arsenic and other mineral poisons, being largely composed of those coal tar products that are well known to be destructive of insect life.

**Mending Tin and Other Ware.**—The use of a "soldering iron" is one of the accomplishments that every boy may easily acquire, and should he afterwards live in the country or elsewhere, at a distance from a tinsmith, he will find frequent occasion to use his skill. There are several contrivances to aid those who cannot use the soldering iron in mending tin-ware. One of these, the "solder-wire," was noticed several months ago, another, suited to mending larger holes, is called the "Copper Patch Plate." This is a sheet of copper, thin enough to be easily cut with ordinary shears; one side of it has a rather thick coat of solder, over which is a film of rosin. To mend a hole in a pan or other vessel, a patch is cut from the plate, enough larger than the hole to extend for some distance all around it. The surface to which the patch is to adhere being scraped clean, that is put in its place, and a heated poker or other iron is held upon it until the solder melts and adheres to the surface of the vessel. To make a good job, take care to fit the patch well to the surface, so that it touches in every part; scrape the surface bright and clean, and do not touch and soil it before the patch is in place.

**Beautiful Iron Work.**—The catalogue of the Racine (Wis.) Iron Works is a most interesting pamphlet, as it shows the great perfection that has been reached by our iron founders. This company makes a vast number of wares used in window gardening, such as Brackets, Pot Stands, Window Boxes, Ferneries, etc., in which tasteful design increases their beauty without detracting from their utility or increasing their cost.

**Milk Cans—Keep Clean.**—Much of the success of many in butter-making depends upon the thoroughness with which they cleanse their milk cans, pails, pans, etc., in fact, all the utensils that are in any way connected with the milk and cream. Some persons cannot make good butter, because they are careless in all the operations.

**Invalid Chairs.**—The best place for a very sick person is the bed, but the convalescent finds a change to a chair of some kind, especially one of the modern invalid chairs, is a great relief. It often happens that a sprain, or it may be a rheumatic attack, or other trouble, will inter-

fere with the locomotion of one who is not otherwise disabled. In such cases a chair in which one can propel himself about by the use of the hands is a great convenience. Cases like these, not to mention the many in which the person is permanently crippled, have led to the invention of a great variety of chairs which are known by the general term of "Invalid Chairs." These often show much ingenuity in their propelling arrangements, as well as in their adjustments, which allow of a change to a great variety of positions according to the desire of the occupant. No chairs of this kind have had a greater popularity than those made by Herbert S. Smith, a concern which father and son have advertised in the *American Agriculturist* these many years. This is the only establishment in this country, and probably the only one in any country that devotes itself to making such chairs exclusively. Where these are the only wares made, one is likely to find a greater variety, and also to get styles to suit particular cases, than where the work is only a part of a general furniture business.

## Nuts and Nubbins.

Hard to beat—an old carpet.  
A floral swell—the dandelion.  
Something gnu—a horned horse.  
Do ships on speaking terms lie to.  
Spring holds the rains this season.  
The king of Greece—Oleomargarine.  
Lap of luxury—when the cat gets cream.  
A plant that flourishes in winter—The cow-slip.  
An undertaker gets a living where another man dies.  
A gentleman named his dog Penny, because it was one sent to him.  
Cats have no fixed political belief. They are usually on the fence.  
A man is like an egg. You can not tell whether or not he is good until he is "broiled."  
An advertisement for a "saddle-horse for a lady of about 350 pounds" is going the rounds.  
We hear of men sowing wild oats, but whoever heard of a woman sowing anything but tar?  
A Western paper heads the marriage of a bachelor of 57 years. "Another Old Landmark Gone."  
"Another old settler gone!" exclaimed the cook when she tossed the egg-shell out of the coffee-pot.  
"Look out for the locomotive when the bell rings," is painted in large letters, so that he who reads may run.  
A Meriden man has a Bible 142 years old. Strange how long a Bible may be made to last by temperate usage!  
"Gentleman," said a farmer, writing to the chairman of an agricultural society, "put me down on your list of cattle for a calf."

Artemus Ward once began a lecture by saying: "Ladies and gentlemen, I possess a gigantic intellect, but I haven't it with me."

Some females have just been arrested in Kentucky for the manufacture of illicit whiskey. This is the first recorded instance of a woman keeping still.

Wife: "But, my dear, I shall catch cold coming down so late to let you in."—Husband: "Oh, no, my love, I'll rap you up well before you come down."

A husband telegraphed to his wife: "What have you for breakfast, and how is the baby?"—The answer came: "Buckwheat cakes and the measles."

One of the saddest and most vexatious trials that comes to a girl when she is married is that she has to discharge her mother and depend on a servant girl.

Photographer: "Now, sir, if you'd look a little less as though you had a bill to meet, and a little more as if you'd been left a legacy, you'll be a picture."

If the deacon will pass the contribution-boxes around on the sidewalks they may be able to scatter the crowds of loafing young men who stand in front of churches.

Young ladies who wish to have small mouths are advised to repeat this at frequent intervals: "Fanny Finch fried five floundering frogs for Francis Fowler's father."

A couple of reporters spent the night in a cell with a man who was doomed to be hanged in Connecticut recently, and in the morning the prisoner was perfectly willing to die.

An Irishman who stood for a long time looking at a ship's anchor was ordered away, but refused to go, saying: "Divil a bit will I stir till I see the man that's going to use that pick."

"What is worse than freckles?" asks the *New Haven Register*. "Corn." They don't show much when you're dressed up, but then if you keep straight, no fellow can step on your freckles."

Patient: "Yes, sir; you are an ignorant blackguard, sir." Homeopathic M. D.: "Well, sir, then you've come to the right person for treatment, as, according to our theory, 'like cures like.'"

An ingenious observer has discovered that there is a remarkable resemblance between a baby and wheat, since it is first cradled, then "thrashed," and finally becomes the "flour" of the family.

A little girl who had often heard her mother speak of her father, who was quite bald, as being a self-made man, asked her one day, if her father was a self-made man, why he didn't put more hair on his head.

In struggling to make a dull-brained boy understand what conscience was, a teacher finally asked: "What makes you uncomfortable after you have done wrong?"—"Father's leather strap," feelingly replied the boy.

At an examination for admission to the bar, the question was asked: "What is the rule in Shelley's case?"—One of the class answered: "It is the same as in any other man's case. The law is no respecter of persons."

A little girl, aged three, went to church lately to see a christening. When, on her return, she was asked what she thought of the baby, she replied: "It was a good baby, it did not cry when the gentleman washed its head."

It is said that a young lady in Penn Yan, N. Y., wears twelve diamond rings on one finger, and the *Norristown Herald* thinks she should also wear a gold band around her head to prevent the crack in her skull from widening.

Smith to Brown, going home from the club in the small hours of the morning: "I'm awfully late, Brown; what'll you say to your wife?"—Brown: "Oh, not much; good morning, my dear, or something of that sort; she'll say the rest."

An Illinois youth, husking corn in a field near the rail-

road, saw a new locomotive, with a red smoke-stack. He became frightened, and ran to the house crying: "That 'ere engine is going to bust, sure; it's red-hot clean to the top of the stovepipe."

A young lady who read that it is lucky to pick up a horse-shoe, happened in a blacksmith shop the other day, and picked up one just made. The surprising suddenness and piercing shriek with which she dropped it showed that it was more than simply lucky.

"Is this my train?" asked a traveller of the Kansas Pacific Railroad depot lounge.—"I don't know, but I guess not," was the doubtful reply. "I see it's got the name of the railroad company on the side, and I expect it belongs to them. Have you lost a train anywhere?"

A small boy, boasting of his father's accomplishments, said: "My father can do almost anything; he's a notary public and he's an apothecary, and can mend teeth, and he is a doctor, and can mend wagons and things, and can play the fiddle; he's a jackass at all trades."

"Do you see that spring over there?" said a settler in Arkansas to a stranger. "Well, that's an iron spring, that is; and it's so mighty powerful that the farmer's horses about here who drink the water of it never have to be shod. The shoes just grow on their feet naturally."

An Englishman at a hotel in New York asked the clerk if there were "oysters in the hotel."—"Oh, yes, was the answer; 'step right in the restaurant; we don't keep them in the office.'—"Egad!" said Mr. John Bull, "I think you misunderstand me, you know; I mean a 'yster, don't you know, a 'lift—a 'helllevator' may be you call it in this country."

The people of a New Hampshire town are so fearfully lazy that when the wife of a minister who had just settled in that town asked a prominent citizen if the inhabitants generally respected the Sabbath and refrained from business, replied: "Confound it, and the farmer don't do enough work in a whole week to break the Sabbath, if it was all done on that day."—*Post*.

"Bub, did you ever stop to think," said a grocer recently, as he measured out half a peck of potatoes, "that these potatoes contain sugar, water, and starch?"—"No, I didn't," replied the boy, "but I heard mother say you put peas and beans in your coffee, and about a pint of water in every quart of milk you sold." The subject of natural philosophy was dropped right there.

The other day a farmer met a friend, who asked him how prospects were out in the country.—"This dry weather is just killing everything," was the doleful reply. Some hours afterward a storm of rain broke over the city, and as the farmer ran in and out of the wet his friend said: "This will do good out your way."—"May be, may be," said the farmer, "but it's mighty rough on them's got hay out to-day."

A clergyman asked his Sunday-school: "With what remarkable weapon did Samson at one time slay a number of Philistines?"—For a while there was no answer; and the clergyman, to assist the children a little, commenced tapping his jaw with the tip of his finger, at the same time saying: "What's this? what's this?"—Quick as thought, a little fellow innocently replied, "The jaw bone of an ass, sir."

As P. T. Barnum was selecting a turkey in one of our markets, the owner drew his special attention to a large fat gobbler. Suspecting it was an antediluvian, Mr. Barnum said, with a smile, "What do you sell that old gentleman for?"—With an air of triumph the owner replied, "I sell him for a profit."—"A prophet! Oh, I supposed he was a patriarch," was the quiet response. The study of sacred history terminated.

Little Edith—"Mamma, and you think if a person is really and truly in love, it would be wicked to deprive her of the object of her affections?"—Mamma: "Why, certainly, Edith, dear, but where in the world did you learn that?"—Edith: "I heard you tell it to Mrs. Jinglejaw to day. And, mamma, I'm awfully in love with that loaf of cake in the cupboard." Edith and the object of her affections were immediately united.

Three Irishmen, who had dug a ditch for \$1, were quite at a loss to know how to divide the pay "aqually." But one of the number had gone to school, and reached division in the arithmetic, so it was left to him. He did it at once, saying: "It's aisy enough. Shure, there's two for you two, and two for me, too." The two received their portion with a greatly increased respect for the advantage which learning gives to a man.

A sad looking man went into a Burlington drug store. "Can you give me," he asked, "something that will drive from my mind the thoughts of sorrow and bitter recollections?" And the druggist nodded and put him up a little dose of quinine, and wormwood, and rhubarb, and epsom salts, and a dash of castor oil, and gave it to him, and for six months the man couldn't think of anything in the world except new schemes for getting the taste out of his mouth.

Mr. C—, pastor of a certain church, had been on very bad terms with his flock for some time. Before his contract with the parish expired, he was appointed chaplain at the state prison. Elected at getting rid of him, the congregation came in full numbers to hear his farewell sermon. Great was their astonishment, when the reverend gentleman chose for his text the following words: "I go to prepare a place for you \* \* \* that where I am, there ye may be also."

Patrick saw a bull pawing in a field, and thought how amusing it would be to jump over, catch him by the horns, and rub his nose in the dirt. The idea was so funny that he laughed to think of it. The more he thought of it, the funnier it seemed, and he determined to do it. He was quickly assailed him over the fence, somewhat bruised, Patrick leisurely picked himself up, with the very consolatory reflection: "Well, it is a mighty fine thing that I had my laugh afoorst."

"Prisoner at the bar," said the judge to the man on trial for murder, "Is there anything you wish to say before sentence is passed upon you?"—"Judge," replied the prisoner, solemnly, "there has been altogether too much said already. I knew all along somebody would get hurt if these people didn't keep their mouths shut. It might as well be me, perhaps, as anybody else. Drive on, judge, and give us as little sentiment as you can get along on. I can stand hanging, but I hate gush."

"William, do you know why you are like a donkey?"—"Like a donkey?" echoed William, opening his eyes wide: "no, I don't."—"Do you give it up?"—"I do."—"Because your better-half is stubbornness itself."—"That's not bad. Ha! ha! I'll give that to my wife when I get home."—"My dear," he asked, as he sat down to supper, "do you know why I am like a donkey?"—"He waited a moment, expecting his wife to give it up, but she didn't. She looked at him somewhat comically, as she answered: "I suppose because you were born so."

A well-dressed lady called at a carpet warehouse and asked to look at some carpets. The goods were shown, every pattern in the shop being spread out for examination. After looking at everything about the place, and driving some very close bargains in the matter of price, the lady selected a carpet for each room in her house, running up a bill which filled the salesman's heart with joy. When all was completed, he asked where the carpets were to be sent. The lady replied, without hesitation, that she would call and let him know; she added, "my husband has just bought a piece of ground, and talks of soon building a house on it. If he does, you know, I shall want some new carpets, and then I will call and order these, as I know the cost."

# PIGS.

## THOROUGHbred AND CROSS-BREED

### OR GRADE JERSEY STOCK.

5 fresh cows, 4 to 8 years old, with or without calves. 5 thoroughbred Jersey Bulls, 1 to 5 years old.

All the above are, or can be registered in the A. J. C. Club Register. 25 cross-breed heifers and cows, 2 to 7 years old. These are a mixture of the two breeds, Jerseys and Ayrshires; several are now fresh, and the balance within the next two months. The best family cows ever bred, all rich milkers and butter-makers; some of them 2 lb. cows, beautiful in form and color. Orders solicited for calves of either breed, deliverable when weaned and ready to ship at 2 to 3 months old. My prices range from \$45 for a high grade heifer calf, to \$400 for my best thoroughbred cow and calf. April, 1880. THOMAS FITCH, New London, Conn.

Address H. H. STODDARD, HARTFORD, CT.

The New Sheep Dip. Little's Chemical Fluid. Non-poisonous, Non-corrosive. Copy Testimonial. It gives us great pleasure to bear testimony to the merits of "Little's Chemical Fluid," used by us on our Lincoln Herds to destroy the tick. It is the best preparation we ever used for that purpose. We have no hesitation in recommending it to all sheep breeders who wish to rid their herds of tick.—T. VALTERS & SONS, 13th June, 1880, West Chester, Pa.—Address for further testimonials and price, T. W. LAW FORD, General and Wholesale Agent, 206 E. Chase St., Baltimore, Md.

## BAT AND TRAP.

As here represented, the articles necessary to play this game are one bat, one ball, and the trap. Any number of persons can engage in the game, from one to five on a side, and it can be played by ladies and gentlemen, or girls and boys. It can be played on the lawn, meadow, or any place where baseball, lawn tennis, or croquet

are played. The ground need not be smooth as for croquet. It is very fascinating, and has as much variety as any other popular game. Rules accompany each game, and they are easily learned.

Price, \$2.00.

Expressage to be paid by the Recipient.

ORANGE JUDD CO., 245 Broadway, New York.

## Creamery Outfits and Butter Makers' Supplies.

Send for Circulars on Creamery and Cheese Apparatus, and Refrigerator Vat, for raising Cream. **Cheese-Box Material** furnished complete, ready to put together.

WHITMAN & BURRELL, Little Falls, N. Y.

## \$10. The Finest Single Breech-Loader in the World. \$10.

### THE PREMIER.

### PRICE TEN DOLLARS.

The **PREMIER** is the best single barrel breech-loading shot gun that has ever been made, possessing as it does all the extras and improvements of a first-class double gun. The Premier is the only single gun with all modern improvements in the barrel, and is the only single gun that looks, handles, or is shaped like a double gun, and in many respects it is preferable to a double gun, especially for glass-ball shooting. Choke bored in the best and most scientific manner.

**All Improvements,**  
TOP SNAP, LAMINATED TWIST  
BARRELS, REBOUNDING LOCK,  
BLOCK STRIKER, PISTOL GRIP,  
PATENT FORE-AND-CENTRE  
HAMMER, (direct fire),  
and CHOKE BORED.  
75 Yards Range.

We are, ourselves, the sole manufacturers of the Premier Gun, and have been making them constantly for the past six months, and we now have the largest stock of single guns in the U. S. In order to reduce our stock during the summer months, we shall retail the Premier Gun at the closest wholesale price, which is \$10. The regular retail price being \$15. No further reduction will be made, and none will be retailed at \$10 after September 1st. This is a rare opportunity to get the finest shot gun of its kind in the world at the wholesale price. They can be readily sold at from \$15 to \$18 in any town in the United States. The PREMIER is the only single breech-loader that will satisfy a sportsman; it is in every way up to the standard of a \$50 double gun, and we use over \$30,000.00 worth of special tools and machinery in its manufacture. The barrel is FINE LAMINATED TWIST, equal to those in \$50 guns, and the stock is fine walnut, hand checked, frames either nickel or cashed, trimmings cashed and blued. Every one is carefully choke bored, and an ATTESTED TARGET goes with each gun. 12 bore, 30 and 32 inch barrel, weight from 6 1/2 to 7 1/2 lbs. 2 1/4 to 3 1/2 inch drop. Use paper or brass shells centre fire. Remember, that the Premier, unlike all other single guns, has all the modern improvements or extras, and we warrant it up to the standard of a Colt or Parker double gun. SPECIAL PRICE UP TO SEPTEMBER 1st, \$10, and when cash comes with order, we give, free, a hard wood compartment gun case, and a set of reloading tools. These are not given when sent C. O. D. Will send C. O. D. on receipt of the Express Agent's guarantee that the gun will be returned free, if not taken. We ask no cash in advance on C. O. D. matter, as we have never yet had a Premier Gun returned. Every gun warranted or money refunded. Address G. W. Turner & Ross, Mfrs. and Dealers in Firearms, 16 & 17 Dock Sq., Boston, Mass., U.S.A.

## American Grape Growing and Wine Making.

BY

GEORGE HUSMANN.

PROFESSOR OF HORTICULTURE IN THE UNIVERSITY OF MISSOURI.

With Contributions from Well-known Grape Growers, giving  
**A WIDE RANGE OF EXPERIENCE.**

### ILLUSTRATED.

The work is a complete guide for novices in the culture of the Vine, and at the same time may be regarded as a summing up of everything of importance and value bearing upon this industry. Special attention is devoted to the Phylloxera, whose destruction of the roots of vines had very much to do in bringing on the collapse of grape growing, and the destruction of the vineyards of France. The experiments and discoveries of Husmann and his associates in connection with this destructive little insect, are, for the first time, presented in this volume, and will prove of incalculable benefit to the grape growing interests of this and other lands.

The book is copiously illustrated with sketches from the author, which add materially to its value.

PRICE, POST-PAID, \$1.50.

## AMERICAN FISHERIES. A HISTORY OF THE MENHADEN.

By G. BROWN GOODE,

Curator U. S. National Museum; Assistant, U. S. Fish Commission; Author of "The Game Fishes of North America;" Special Contributor to American Agriculturist.

WITH AN ACCOUNT OF THE AGRICULTURAL USES OF FISH.

By W. O. ATWATER,

Professor of Chemistry, Wesleyan University; Special Contributor to American Agriculturist.

AND AN INTRODUCTION, BRINGING THE SUBJECT DOWN TO DATE.

WITH THIRTY PLATES.

PRICE, POST-PAID, \$2.00.

## Twenty Years of Inside Life in WALL STREET,

Or, Revelations of the Personal Experience of a Speculator.

Including Sketches of the Leading Operators and Money Kings—The Great Rises and Panics—The Mysteries of the Rings, Pools, and Corners, and How Fortunes are Made and Lost on 'Change.

By HON. WM. WORTHINGTON FOWLER.  
FULLY ILLUSTRATED.

Some ten years ago Mr. Fowler published a Volume, giving Ten Years of Experience in Wall Street. The work received the highest encomiums, and met with a very large sale. This New Volume brings the Author's experience down to the present time, thereby presenting in detail all the leading facts and incidents which have transpired in Wall Street for twenty years past. Mr. Fowler is a graduate of a New England College, was formerly a State Senator of Connecticut, is widely known as a journalist, and tells the story of his personal experience in a graphic, entertaining style.

12mo. CLOTH. PRICE, POST-PAID, \$1.50.

Either of the above books sent post-paid on receipt of price, by

ORANGE JUDD COMPANY,  
245 BROADWAY, NEW YORK.

**GOOD NEWS! GOOD NEWS!**

**FOR ALL YE BOYS, FROM 5 TO 105 YEARS OLD!**

Scroll or Fret Sawing is one of the most delightful amusements, combining pleasure, utility, and a development of taste and skill. Every home, however humble or magnificent, is more beautiful if adorned with brackets and other work produced by home hands. Hundreds of thousands of such homes now exist, where only the slow and tedious hand-frame fret saws have been available. More

Fig. 1.—BEACH'S FRET SAW READY FOR USE.

recently the foot pedal and multiplying wheels have come into use, and the increasing demand has tended to cheapness and improvement. We are now happy to announce another **LARGE ADVANCE** in

**Perfection, Cheapness, and Portability,**

by which is secured stronger, better working machines; a material reduction in price, and a great saving in cost of carriage or delivery, as well as in storage room when not in use, with sundry other improvements and advantages.—All the above are secured in

**Beach's New Folding Fret Saw.**

Figure 1 shows it ready for use, while in half a minute or less it can be folded (without removing the saw) to the form, figure 2, occupying but a quarter of the space, to be set away, or put in a small box for sending anywhere at small cost for carriage. By a simple arrangement the table is lowered to a convenient working height for a boy of 5 or 6, or raised high enough for the tallest man, and at every height it stands firmly.

It has a tilting table, and will execute very fine scroll-work or inlaid-work. The clamps will firmly hold any saw, from the finest No. 00000, up to No. 10; they are readily and quickly inserted or changed. A space of 20 inches behind the saw allows quite as large pieces to be worked as any other instrument of the kind in the market.

By an ingenious arrangement, there are no dead centers, but the wheel starts right off the moment the foot presses the pedal, while it can be instantly stopped by simply pressing the knee against a brake. The upper clamp is hinged to be thrown up for changing the saw, or for inside work. The working parts are iron or steel, finely fitted, securing great durability, while the frame, of tough white ash, or other tough timber, is formed to secure the greatest strength. The whole is so simple that a **CHILD CAN WORK IT**. Parents will appreciate the convenience of such an instrument, of full size, yet quickly folding up so as to be set in the corner of a closet if desired. Though as strong and durable as any one could desire,

Fig. 2.—THE SAW FOLDED.

**The Weight is only 15 lbs.**

With all the above advantages, and its great superiority over any other hitherto produced

**The Price is only \$2.25,**

which includes full instructions, so that a beginner can go to work at once. It is packed in a neat box and is delivered to any express office in New York City **FREE**. The small space required, and the lightness, will reduce the cost of carriage very greatly, as compared with other machines for similar work.

The Editors and Publishers of the *American Agriculturist* were so pleased with this new machine that they at once secured the control of it for the benefit of their readers, though it will be supplied to others as soon as it can be produced in sufficient quantity. It will be forwarded by express or otherwise, as directed, in the order of calls for it, at **\$2.25** each.

## Books for Summer Reading.

### Canoe and Camera; or, Two Hundred Miles Through the Maine Forests.

**JUST PUBLISHED.**

Together with a map prepared expressly for the work by WM. R. CURTIS, C. E.; beautifully bound in cloth and gold, containing sixty life-like illustrations by such artists as True Williams, Benjamin Day, and Aug. Will. This is one of the most elegant books of the kind ever published, describing a tour of two hundred miles through the vast forests of the Pine Tree State, and containing full instructions and directions as to the most successful and enjoyable modes of visiting them. The Author has already made himself widely known by his contributions to the public press regarding this interesting region of country. His accounts of the route, the fishing regions, the adventures and the scenery, are given with much spirit, and should draw to Maine a crowd of pleasure seekers. An additional charm is its ORIGINAL ILLUSTRATIONS, SIXTY IN NUMBER, drawn from photographs taken on the spot. Those who have hunted or fished in the vicinity described will recognize the truthfulness of these illustrations. To those unable to visit this charming region, the book will be found as thoroughly fascinating as many of the best volumes of fiction. A large Map accompanies the book, showing the entire region traversed, including the Mooshead Lake region. By THOS. SEDGWICK STEELE.

CHARLES D. WARNER writes of this charming volume:

"It is one of the handsomest books of the season, fully illustrated by drawings from the author's own pencil, and from his photographs. Many of the drawings are not only picturesque, but interesting as views of the wild scenery, which the author describes. The author has taken a fresh and enjoyable trip, which others may enjoy with him, by the aid of pen and pencil."

*Forest and Stream* says: "It is a superb volume. The country explored and described comprises a Territory rich in beautiful scenery, and well supplied with game and fish."

The *Religious Herald* says: "It makes one feel as if one must go over the same route."

Square 12mo. PRICE, POST-PAID, \$1.50.

### Camps and Tramps in the Adirondacks, and Grayling Fishing in Northern Michigan.

**JUST PUBLISHED.**

A record of summer vacations in the wilderness. Those who are fond of the woods will be delighted with this new book. It bristles with information on shooting and fishing, and may be relied on as an accurate guide to all the chief points of attraction in this famous region, and gives valuable suggestions on Camping Outfits, Fishing, Hunting, etc., etc. The Author, who is an eminent lawyer of Central New York, has long been famous for his jaunts into the wild regions, explored and unexplored, of the country, and for his vivid entertaining descriptions of scenes and adventures by the way. By A. JUDN NORTHROP.

That veteran journalist, GEORGE DAWSON, says in the *Albany Evening Journal*:—"Those who are fond of the woods will be delighted with *Camps and Tramps*. The chapters on Grayling Fishing are exceedingly well done, and we say this because we know all about it—the waters fished and the sport to be derived from angling for this gamey fish. The book is a pleasant and timely addition to fish lore and angling literature."

The *Churchman* says: "As a narrative it runs along with quite as much liveliness as it would if the author were writing a fiction, and we are favored not only with well drawn descriptions of scenery, but also with entertaining conversation and life-like exhibitions of human nature."

Handsomely bound in Cloth. 16mo. PRICE, POST-PAID, \$1.25.

### Trouting on the Brule River; or, Summer Way-Faring in the Northern Wilderness.

**JUST PUBLISHED.**

The Author is well known both for his literary labors and ardent love of the rod and gun. In this beautifully gotten-up volume he narrates the adventures of himself and party during weeks of Camping Out in the wild regions of Northern Wisconsin and Michigan, along the Michigami, Paint, Trout, Brulé, and Menominee Rivers, which abound in Fish and game of every description.

The Volume gives a general description of these sporting regions, which are beginning to attract general attention, presents a complete map of the same, and tells all about the best routes to get to them. By JOHN LYLE KING.

The *Chicago Field* says: "It relates in a graphic, brilliant, and amusing style the many entertaining incidents of several weeks' journeying, sporting, and open-air life in the wilderness, and portrays with detail and fidelity, the actual life and fun of Vacation Way-faring. A valuable addition to the book is the valuable information not hitherto easily accessible, in relation to portions of The Northern Wilderness, and the means of reaching and enjoying them."

12mo. PRICE, POST-PAID, \$1.50.

### The Dogs of Great Britain, America, and other Countries.

Their Breeding, Training, and Management in Health and Disease, comprising all the essential parts of the two Standard Works on the Dog by Stonehenge, thereby furnishing for \$2.00 what has hitherto cost \$11.25. The book contains over One Hundred beautiful Engravings, embracing the most noted dogs in both Continents. The Volume gives full directions for selecting the best dogs for the purpose required, and for keeping them in health and training.

The *New York Tribune* says: "The author is regarded as the highest living authority on the subject."

The *New York Commercial Advertiser* says: "It is the cheapest and best book on dogs ever issued in this country."

The book is elegantly bound in black and gold, printed on tinted paper, and makes, to quote from the *New York Sportsman*, "a most superb volume."

12mo. Cloth. PRICE, POST-PAID, \$2.00.

### Practical Taxidermy and Home Decoration.

One hundred and twenty-five spirited illustrations; an entirely new and complete, as well as authentic work on Taxidermy. Just the book for those desiring to preserve the skins of animals, game birds, fishes, etc., etc. By JOSEPH H. BATTY, author of "How to Hunt and Trap," Taxidermist for Government Surveys, and many of the leading Colleges, and Museums, of the United States.

12mo. Cloth. Tinted Paper. PRICE, POST-PAID, \$1.50.

VOLUME XXXIX.—No. 9.

NEW YORK, SEPTEMBER, 1880.

NEW SERIES—No. 404.

THE SEMI-PALMATED, OR "WILLET" SNIPE (*Totanus semipalmatus*).—Drawn and Engraved for the American Agriculturist.

In the Middle States the species of *Totanus* shown in the accompanying engraving is known to every coast hunter as the "Willet," or "Willet Snipe."

This common name is derived from the peculiar note, *will-willet* or *will-will-willet* which the bird produces when rising for flight. Farther south this snipe is generally known as the "Stone Curlew." The "Willet" is seldom met with far inland, it preferring the sea coast, and especially that portion in the vicinity of large rivers. During the breeding season it is very generally found from the mouth of the Mississippi to New York, and occasionally as far north as Boston. In autumn it returns to the coast of Georgia, Florida, and the Gulf States, where it spends the Winter in the extensive salt marshes that abound in that region. It also occurs to some extent on the western coast. In the Middle States—New Jersey, Delaware—the "Willetts" make their appearance about the fifteenth of April and begin to breed a month later. They retire to the seclusion of the large salt

marshes where they can build their nests and raise their broods of young in comparative security.

The nest is upon the ground and built out of the coarse herbage of which the rank marsh grass affords an abundance. The eggs are usually four in number, measuring two inches in length by one and a half in breadth, and are much flattened at one end. During the mating season the birds are unusually noisy, filling the air with their sharp cries, but later they brood in silence, unless disturbed. "Both birds incubate, sitting alternately day and night. The young run about on leaving the shell and are carefully fed by their parents."—The food of the "Willet" consists of small crabs, fiddlers, aquatic insects, etc., which they secure largely by probing in the mud bars with their long bills. This Snipe is at all times a shy and wary bird, and to be approached by the hunter with the greatest caution. The sight of a gunner produces the greatest alarm in the birds, which rise on the wing and give out loud angry cries, constantly en-

deavoring to allure the hunter away from the spot where their nest and young are concealed. Audubon's method of hunting them was to employ a well trained dog, and to conceal himself in the tall herbage of the marsh. The birds will fly not far above the dog and follow him, so that when the dog approaches the hunter the birds are taken on the wing. But this cannot be long continued as the birds will soon fly away to some place of safety.

The plumage of the "Willet" is soft, and a mixture of brown, black, and white; the back is a brownish gray; the breast being white; the bill, feet, and legs, are light blue; the wings long and acute; the tail short and made up of twelve rounded feathers. They have a summer and a winter plumage which differ considerably; the former is shown in the engraving. The males are smaller than the females, the former averaging seven ounces, the latter ten ounces. In the engraving the female is in the foreground, and therefore the contrast in size is apparently somewhat exaggerated.

**Seedling Fruits.**—“M. M. M.” Manitoba. There is no regular time from the seed at which apples, pears, etc., will bear, as they vary greatly among themselves. Generally the seedling must be from 10 to 15 years old, before it will bear fruit, but they sometimes bear at 6 to 7 years old. The time may be hastened by grafting the seedling upon a vigorous fruiting tree.

## Calendar for September, 1890.

## AMERICAN AGRICULTURIST.

NEW YORK, SEPTEMBER, 1890.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

**Sowing Fall Grains.**—The leading farm work for this month in many localities is the sowing of the fall crops. One can not expect that the best harvest will follow a careless preparation of the soil, and an imperfect sowing of the seed. The young plants should get well rooted before winter sets in, and in order to insure this, the soil should be deep and mellow. Wheat requires a soil well pulverized, but compact, with fine tilth of the surface, for a seed-bed. There may be lumps on the surface of the soil, but the seed should not be surrounded by them, otherwise the plants will be very uneven, and many grains will not start at all. If the soil is lumpy, as it is in many cases,

Use a Roller immediately after the plow, or after the harrow has been used once. This is the only proper use of the roller on fall sown fields. To roll the ground after the grain is sown is a mistake; it gives to the surface a smooth and pleasing appearance, but it is much more inclined to crust over; besides this, the protecting coat of snow is not held in winter as it would be if the surface was left rough. Besides having the soil in a proper mechanical condition, through the means mentioned above, it must be provided with a good supply of

**Plant Food.**—The young plants should be well fed, that is, have a plenty of nourishment in such a condition as to be readily taken up and digested. Such food is furnished by thoroughly decomposed barn-yard manure; but when it is not to be had in sufficient quantities, some good artificial fertilizer as a superphosphate may be used with profit.

**Selecting Seed Wheat.**—Sow the best seed to be found, even if it costs a little more than that taken from the ordinary bin. It is a gain to pay double the market price for grain that is clean, plump, and has been grown for seed with special care. Much depends upon the variety—the Clawson at the present time is taking a high rank for yield in many localities throughout the wheat growing region.

The Hessian Fly is the most troublesome upon the early sown wheat—that sown after the 15th

of this month is not generally damaged—but it makes smaller growth before winter sets in, and so far as that goes it is a disadvantage to sow late, excepting on well prepared land. A farmer of our acquaintance (in the State of New York) for many years sowed his wheat the first week in October, and his average yield has been over 40 bushels per acre. He was first led to practice late sowing to avoid the ravages of the Hessian Fly, but the practice proved so satisfactory that it was continued after the fly had disappeared. His land was in high condition, and a top-dressing of fine manure was applied to give the young plants a good start. It may be better to sow late if a thorough preparation of the soil is thereby secured.

**Water Furrows.**—If the land is not well drained, when all else is done in the wheat field, make the necessary furrows with the plow, for carrying off the surface water during heavy rains.

**Seeding to Grass.**—Grass seed may be sown a few weeks after the grain. Thrifty growing timothy will frequently retard the growth of the grain if sown as early as the wheat crop, and clover seed is best sown in the spring after or with the last snow.

**Turnips** should be kept free from weeds and the soil loose and mellow. Proper thinning is important; a single root needs from 9 to 15 inches in the row to grow to its best. On rich lands white turnips may still be sown and a good crop expected.

**Beets and Mangels** that were sown early, may be harvested this month; if left in the ground they become hollow and dry. Wheu pulled put them in long heaps, with the tops or straw laid over them; to be afterwards covered with earth, to protect them for the winter, or taken to the root cellar. Care should be taken that the roots do not heat at any time either in the pit or cellar.

**Buckwheat.**—This tender crop should be cut before the first frost injures it. The grain shells badly when the plants are dry, therefore cut it in the morning when the dew is on. The cut crop after standing a few days will be dry and ready to thresh, which had best be done at once. If a machine is used, remove the concave, or the cylinder teeth will otherwise break the kernels. The grain should be cleaned at once and spread out as thinly as possible, as it is very apt to heat, and become almost worthless, if left in large heaps.

**Beans** are injured by heavy rains; when ready pull them and stack around the poles driven in the ground; cover the stacks with straw. In pulling, leave them in rows for a time to cure, and if rain threatens they can be gathered quickly in stacks.

**Corn.**—Early corn will be ready to cut this month. As soon as the grain is glazed it is ready to be harvested, and the stalks will be much more valuable than if left to be killed by frosts. The seed for next year should be selected before the cutting has begun. The tops of the selected stalks may be broken down as a mark and left standing when the others are cut and shocked.

**Shocking** is an important matter and should be done with care. If the stalks are not well set up and properly tied, the shocks fall in all directions and the fodder is damaged and the husking made more difficult. Bands of rye straw, or even of willow, may be used with advantage.

**Potatoes.**—Early ones should be dug at once; rains will otherwise start them into growth and do much injury. The last brood of “bugs” should be destroyed, as it is these that furnish the early brood next season. It is a good plan to sort the potatoes as they are gathered, thus saving much labor in handling them afterwards.

**Sheep.**—After the roots have been removed from the field, the sheep should be turned in that they may pick up the small, imperfect roots and the scattered leaves. This will accustom them to the change of food that must soon come. If early lambs are not desired, the rams must be kept from the ewes, or otherwise be aproned or “bratted.” It is an important matter that the ewes that are to bear lambs should be well fed, and begin the winter in good condition. A little grain fed to the ewes now will do much to insure strong lambs. Cows that are giving milk should be fed liberally,

and not allowed to fall off now, as they can not be brought up again when cold weather sets in. Some kind of feed, as bran or meal, should be used to help out the failing pastures. Corn fodder is excellent to piece out with at this season, and a patch of it should be found on every farm. It is important that the cows have a plenty of good, fresh water, especially as the herbage does not now afford the abundant juices of the spring growth.

**Clover Seed.**—The second crop of clover for seed can be cut with the ordinary reaper. Some prefer to attach a short frame of strips of wood covered with cloth to the cutting bar of the mowing machine, the clover being gathered upon the cloth and raked off. This makes a much lighter cutting machine. The straw and chaff are useless for hay, and need not be preserved from the weather. They may be used for litter in the barn-yard or stable.

**Whitewash.**—A good way of cleaning stables, sheds, etc., is to give them a coat of hot lime-wash. Make a barrel of the wash by slaking a bushel of fresh lime in a pork or other water-tight barrel, filling up the barrel after the slaking is done. A ready method of applying the wash to coarse work is to use a Fountain Pump, or other hand force pump. With one of these the whitewash can be thrown upon the walls, and into every corner and crevice, until every part is completely covered.

**Machinery.**—Harvesting and other farm machinery that is to be used no more for this season should be cleaned and stored away. The bright parts may be kept from rusting by applying a mixture made by melting together one pound of fresh lard and a lump of resin the size of a hen's egg, stirring as they cool. The bearings should be well wiped, and afterwards given a thin coat of castor-oil.

**Sundry Matters.**—Coarse herbage and weeds not in seed may be cut and placed in the barn-yard as an absorbent of liquid manure.... A number of little jobs can be done now that will aid greatly in making things comfortable, and will pay a good interest upon the time invested.... We again urge all to attend the fairs, doing it with the eyes open to catch any new ideas that may be of use at home. There is much to be learned if the time at the fairs is rightly employed. Make it a point to go and take the family, and, best of all, try for one or more prizes, and thus have a more direct interest in these instructive exhibitions of the products of the farm.

### Notes on Orchard and Garden Work.

As already noted elsewhere, the apple crop is of almost unprecedented abundance; pears for the most part offer but a moderate crop, though the most popular variety, the Bartlett, so far as we have observed, is fairly abundant. But the grapes—they are almost equal to the apples in the bountiful yield. It seems as if we never saw wild vines so loaded in our rambles through the woods as they appear to be this year, while cultivated vines present a sight that can not fail to delight the heart of the vineyardist. This abundance may not be best for the fruit grower, but it is a grand thing for the fruit consumer.—Already, early in August, Concord grapes are retailing on the street for 5 cts. per pound. We hope to see the time when every man, woman and child, the whole country through, can have all the grapes they can eat during the season. It is as easy to grow grapes as it is to raise corn, and those who cultivate them must make the increased quantity compensate for the low price.

### Orchard and Nursery.

**Apples** are abundant this year, and it will not pay to market any that are not of the best quality. See the use of the bag in picking, with illustrations of the manner of emptying it in the barrel on p. 348.

**Peaches.**—A single over-ripe peach in the crate or basket will often make a great difference in the selling price in the market. Peaches for market should always be simply mature, but never soft.

**Pears** of all varieties are best when ripened off of the tree. Some varieties, such as Clapp's Favorite, are worthless if allowed to remain too long upon the tree, but if picked as soon as mature, and allowed to ripen, are among the best. In no case

should the fruit be shaken from the trees. Use a picker for those that can not be otherwise reached. The fruit of the choicest larger varieties may be packed in shallow crates, each specimen wrapped in tissue paper. For general shipping, half-barrels are found the most convenient in handling.

**Cider.**—The early windfall apples may be utilized by making into cider, which will answer for making vinegar. The best cider can only be made from perfectly mature fruit later in the season. Those with a large orchard can profitably keep a small mill and press, and work up the apples as they accumulate; they are made of all sizes, and a small one is not costly. It should be understood that

**Budding** is one of the important labors of the present month. The precise time depends upon the condition of the stock. The work may be continued so long as the stocks are growing. After the buds have become firmly set the ties should be cut. That the buds have "taken," as it is termed, will be known by their remaining green and plump.

**Planting.**—While we are in favor of fall planting wherever the climate is favorable, it can not be recommended indiscriminately. In all localities where there is a long and mild autumn, it is preferable to spring planting. At this season the soil is warm and mellow, a condition favorable to the healing of bruised and cut roots and the growth of new ones. There is more time at this season that can be given to the work, which need not be hurried, and this with the better condition of the soil insures much more thorough work. The trees become established and get an earlier start in the spring, and are the better able to withstand a drouth that may come in mid-summer. The earlier trees are planted after completing the year's growth the better. A mound of earth around the base of the newly set tree serves to keep water from settling around the roots, acts as a support, and protects the base from the attacks of mice. If trees are to be set in the spring, it is best to prepare the ground now, secure the trees, and heel them in in a dry and safe place, to be in readiness in spring.

### The Fruit Garden.

**Blackberries and Raspberries** start so early in the spring that when practicable they should be planted in the fall. *Blackcap* Raspberries, and a few varieties with red fruit, are only to be propagated from the tips of the long pendent branches. If it is intended to propagate these, some of the canes should be left uncut for the purpose. If left to themselves the new canes naturally bend over and grow downward until they reach the earth, where their tips strike root, to form new plants. In cultivation it is well to help them by placing a little earth on the ends of the canes in order that they may not be blown about by the winds.

**Currants and Gooseberries** may be pruned so soon as the leaves have fallen. Cuttings may be made now and planted in rows a few inches apart with one bud above the surface, taking care to press the earth very firmly against the base of the cuttings. If put in early, roots will be formed this season.

**Grapes.**—The scissors made for the purpose should be used in gathering, as they hold the clusters and avoid handling the fruit, which, by removing the "bloom," greatly injures its appearance, and consequently its sale. Trays should be used in which the grapes are placed and conveyed to a cool place, where they are left for a few days for the skin to harden, after which the fruit may be packed in small boxes, when it is ready for market.

**Packing Grapes.**—Both thin wooden and paper boxes are used, and should hold from three to five pounds. The bottom of the box is removed and the grapes laid in carefully. The box should be full enough to require slight pressure to bring the bottom in place, but not so as to bruise the fruit.

**Strawberries.**—Keep the old beds clean of weeds, and remove all runners not needed for new plants. The planting of new beds is given on page 354.

### Kitchen and Market Garden.

As the cooler weather comes on the late crops will make a more rapid growth than during the hot and dry weather of summer. The late weeds

will also grow vigorously, and there should be no relaxation of vigilance with them. When a crop is removed, the ground should be cleaned and the weeds and refuse disposed of by burning or composting. The weeds may be kept down afterwards by an occasional running of the cultivator.

**Celery** should be making a rapid growth now, and will need all the encouragement of clean culture and frequent stirring of the soil. If some is wanted for early use, a number of the most forward plants may be straightened up and have the earth drawn around them, increasing the banking at intervals of a week or so. This is only for present use, the winter supply should be so treated next month.

**Cabbages and Cauliflowers.**—Frequent use of the cultivator or hoe will promote growth. If the late plantings are backward, a little guano or other concentrated manure will be of great benefit. Seeds for plants to be kept over winter in cold frames for next spring planting, are to be sown now. Only the early varieties are thus treated. In the vicinity of New York City, gardeners sow about the middle of the month, each one having his favorite date. If sown too early the plants will be too large for wintering, and if sown too late, they will be too small. The seed is sown in rich soil.

**Corn.**—A quantity should be dried for winter use. The earliest and best ears should be saved for seed. As fast as the ears are taken from the planting, cut up the stalks and feed to the stock, or cure for winter use.

**Cucumbers.**—Let none ripen except the few needed for seed, as it is very exhaustive to the plants. Gather for pickles every second day.

**Martynias.**—Gather the fruit for pickles while still very young and brittle.

**Melons** ripen best if they are turned occasionally.

**Sweet Potatoes.**—Do not allow the vines to strike root at the joints. The largest potatoes for early use may be pulled from the rows, the smaller ones being left to grow through the season.

**Spinach** for use next spring is sown, in the latitude of New York, between the first and middle of the month, in drills 15 inches apart.

**Tomatoes.**—Destroy the large worms by hand-picking. When the fruit is most abundant make a supply of catsup. Gather the green fruit before frost comes for green pickles, etc.

**Turnips.**—The Red-top, Strap-leaved, and other flat kinds may still be sown with hope of a good crop. Hoe and thin the earlier sown.

**Seeds** should not be saved from the leavings of the crop. Select the earliest and best plants and mark them for seed, giving them special attention. It is not best to save the seed of plants that will mix, as the melons, squash, corn, etc., if more than one variety is grown in the vicinity—only mongrels will result. It is cheaper to buy most seeds.

### Flower Garden and Lawn.

Now that the hottest days are passed, the grass will grow more rapidly and the lawn mower will be more frequently used. Annual grasses, especially the "Finger Grass," will spring up, but as it lasts for only the season, if it does not seed it will give but little trouble hereafter.

**New Lawns** may be made and the grass seed sown this month. Fall sowing is preferred to that in spring if the season is favorable for its getting a good start before winter comes.

**Cannas.**—Both flowers and foliage should be making a fine display now. Prolong the bloom by cutting away the stalks as soon as the flowers fade.

**Dahlias.**—A large plant will frequently need more than a single stake to support its many spreading and flower-laden branches. Unless well supported the branches break down, just when the plant ought to be at its best. Remove the blooms as they pass their prime.

**Chrysanthemums.**—Coming when nearly all else is gone they deserve more general cultivation for both their lateness and beauty. If potted, they can be kept in bloom for several weeks in the greenhouse or window. Those wanted to flower in doors

should be potted when the buds are well formed, and shaded a few days.

*Geraniums* should make a fine show of bloom now. Make cuttings now for next year's stock.

*Ornamental Trees and Shrubs* may be set out in autumn. In removing evergreens the chief point is to prevent the roots from becoming dry during the operation. This is by many regarded as a favorable time of year to move them.

*Herbaceous Perennials.*—Fall is the best time to transplant many of these, as those like the Pæony will not bloom the same year if moved in the spring.

### Greenhouse and Window Plants.

All plants to be taken in when frosts are expected, should be in readiness. The houses should also be in order for the hurried time of moving in. In bringing in the plants it is best to do it a little while before the cold comes on, in order that they may not be injured, and more time can be given for clearing of insects, etc. Begin with the most tender varieties. The house plants should go into a room where the windows can be left open, in order that they may by degrees become accustomed to the confined air of the living room.

*Soil, Pots, etc.,* needed during the winter, are to be provided now.

*Seeds of Annuals,* such as Candytuft, Sweet Alysium and Mignonette may be sown. Other sowing for a succession of bloom may be made later.

*Hanging Baskets* may be filled now and hung on the piazza until cooler weather.

*The Roses, Carnations, etc.,* that are to flower in winter should be taken up, potted, and put in a shady place until they recover.

*Slight Frosts.*—When these come early in the season provide a covering for the choicest plants by spreading sheets or even newspapers over them.

### How to Clean Wash Pipes and Sink Drains.

We hardly know the value of the plumber's work which disposes of the wastes of the family, until the pipes become obstructed, and the old-fashioned slop pail has to do the work of gravitation. Then there is loud lamentation in the family; Bridget's work is nearly doubled, and the mistress is threatened with notice of early leaving. We have had an experience in this line which ought to benefit all the house-keepers among the village and city readers of the *American Agriculturist*. Nothing is more common than partial obstructions in the outlet of the wash-bowl or bath-tub, where these conveniences are fixtures in the dwelling. Hair or lint gets in and other obstructions accumulate until the water nearly stops. If a stick is used the foul matter accumulates below, and the plumber has to be sent for, and you have to pay for his skill and time in making a free passage for the water. The best thing to remove these slight obstructions is a rubber force cup, or half globe, about three inches in diameter fastened at the apex to a handle about four inches long. If this is put over the mouth of the waste pipe and pressed downward, it forces a column of air or water against the obstruction in the pipe and removes it. It will remove a slight obstruction in any part of the pipe. The cost of such a force cup is about fifty cents. We think we have saved five dollars in plumber's bills by using one of these cups, as it has been needed during the last three years. Plumbers do not like to keep them for sale for obvious reasons, but you can find them at the drug or rubber store. A more serious matter is the obstruction of the waste-pipe from the water closet and sink, usually a four-inch glazed earthen pipe emptying into the cesspool or street sewer. A recent case of this kind revealed, upon examination, an inch and a half coating of grease upon the inside of the pipe—the accumulation of a dozen years or more from the waste of the sink. This might have been prevented by the occasional use of potash or soda dissolved in hot water and poured into the waste pipe of the sink. W. C.

## An Important Supplement.

All our readers will be interested in the large Supplement with this number, which includes the Premium List for the forthcoming volume. Attention is invited to pages 377 and 378, which explain the object of premium-giving, who may receive premiums, etc., and will answer some objections to the system.

Please note on page 378, the "Extra Long Year," that all new subscribers for 1881 coming in from now onward will receive the remaining numbers of this year, issued after the receipt of their subscription, *without* extra charge. This offer applies to all new subscribers, whether in premium clubs or not. We trust our friends will take this occasion to invite their friends and neighbors to now become readers of this Journal. We shall take good care to make the paper eminently worthy of their perusal.

The Descriptions and Illustrations of a large number of excellent articles, in great variety, on pages 379 to 404 inclusive, of the Supplement, will interest all our readers, even if they care nothing for the Premium Offers.

Carefully Preserve the Supplement to this number. It will be useful for reference on many points all through the year, while its premium offers hold good from now to July 1, 1881.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**Where to Get Things Wanted.**—Many thousands of letters come to the Editors every year (some with and some without "return postage"), asking where they can obtain from trustworthy parties, implements, animals, poultry, seeds, plants, fertilizers, and a great variety of other things, all of which questions we try to answer when we can. But nine out of ten of these letters, and much valuable time of both writers and respondents, would be saved, if the inquirers would take the little trouble required to just look through the advertising columns, where usually, in one number or another, several parties announce the very things asked about. We try to keep out all parties not trustworthy. If any mistake occurs, after all possible care, we can only acknowledge to having been deceived, for we do not admit any advertisers whom we would not ourselves patronize when wanting the things they offer. (The Editors have the "veto power" over any and every advertisement proposed for these columns.) It will always pay to read through the business columns to see what is offered and by whom, and useful hints are often derived from reading what others say and how they say it. New ideas are thus started up in one's mind.—When corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**The Fair List.**—The attention of our readers is called to the Fair List to be found upon pages 367 and 368. We return our thanks to the Secretaries and others, who have favored us with Premium Lists of their fairs, and wish that every fair, small or large, may be a success.

The most important public feature of the extraordinary Premium List in the supplement, is the opportunity afforded to individuals, and to communities, societies, etc., to secure **GOOD BOOKS** on various subjects, including Agriculture, Horticulture, and other topics, **WITHOUT COST**, except transportation. By turning to page 380, it will be seen that any number of persons, from ten upwards, now contributing \$1.50 a piece can each have the *American Agriculturist* from Oct. until the end of 1881, and at the same time, without further expense, secure for the common use of all, good Books of their own selection to the amount of \$10, \$20, \$50, or even \$100 or more.—It only needs some energetic public-spirited leader, in every neighborhood to secure this much desirable result. One of the club can be appointed keeper of the books, and they can circulate from house to house until all read them. They will be a library of reference for all, for diseases of animals, and on a thousand other topics.—If this is not done by combined effort, any individual may collect a club of subscribers, and receive the books for his own individual property, to be loaned out or not as he may choose.

**Our Associate, Mr. Orange Judd,** has been appointed an Indian Commissioner by the President. Though the appointment was a surprise to him, Mr. Judd accepted it, believing that it presented a wide field for philanthropic labor, and he is now on his way to visit the various Indian tribes scattered through the Far West. The universal expression of opinion from the press indicates that the public regard this as an appointment eminently fit to be made. During Mr. Judd's absence we are promised many sketches from him of unusual interest to those engaged in agricultural pursuits. Old readers of the *American Agriculturist* are aware that he is a close observer, and describes what he sees in a graphic and entertaining manner. His letters will constitute a most valuable feature of the paper during the next few months.

**"Experiment Stations" not New.**—We are apt to look upon the various methods for the improvement of agriculture as modern, and give little credit to the fathers for what they have done. We came across an illustration of this in a brief glance at the excellent agricultural library of Prof. Miles of Houghton Farm. The works issued two and three centuries ago are not so numerous as those of the present day, but they show that farming, gardening, and rural pursuits generally, occupied nearly as large a place, proportionally, as they do in our literature now. In a book of 303 pages now before us, printed in 1655, (325 years ago) entitled Samuel Hartlib, His Legacy of Husbandry, p. 89 § 20, on Deficiencies in Agriculture, we read: "2. Deficiency, is, that Gentlemen try so few experiments, for the advance of this honest and laborious calling; when as many experiments might be made for a small matter; for half a Pole square, will give as certain a demonstration, as an Acre; and a Pottle [2 quarts] as an Hogshhead. I hope in time there will be erected a College of Experiments, not only for this, but also the Mechanical Arts." "3. Deficiency, is, that Gentlemen and Farmers do not meet and communicate secrets of this kind, but keep what they have experimented themselves, or known from others; as Sybils leaves." "5. Deficiency is, that men do usually cover great quantities of land, yet cannot manage a little well... A little Farm well tilled is to be preferred...." All sound teaching is not new.

**Sign Your Name!**—When a letter is full of information, we are pleased to know from whom it came and to acknowledge it, which we cannot do when no name is given. If direct questions are asked, the omission of the name is all the worse for the sender, as he or she must go without an answer. Always sign your full name—not simply the initials—to even a postal card that you take the trouble to address to us.

**The Clover Crop.**—It is very seldom that one hears of a farmer who says he has grown too much clover, that with him the clover seed he has sown has not been his best manure. A rotation that does not have clover in it shows that either the system of management is at fault, or it is one fitted to some peculiar circumstances. Clover does not have one single good quality in its favor, but a number of them—not the least of which is its production of a large amount of valuable fodder in two or more cuttings, if for hay; and it makes a fine pasture if the crop is used in that way. The good influence of the clover crop is felt for years in the better corn, wheat, etc., that follow, and this comes from the fact that the clover plant is a deep feeder and brings up a large amount of food elements from the subsoil and deposits it in the larger roots near the surface. As these roots decay the succeeding crops take up the nourishment from them. A growing clover field is a food-gathering, and food-producing, soil-improving, and altogether a very valuable crop upon the farm.

**"Don't Like the Premiums."**—An old subscriber, whose opinion and good will we highly regard, writes: " \* \* \* I don't like your premium business. Why not abolish it and give every subscriber the benefit of the premiums \* \* \* " We would like to exchange places with our friend for a little while, we enjoying his quiet life, and he taking full charge of the publishing business. He would get some new ideas in one year, or at least in twenty-seven years as we have done, provided he did not wear out before the end of the time, as nine-tenths of the papers we have seen started, have done. Elsewhere (page 377) we have explained the theory of giving premiums, and let us just add here, that every subscriber *does* enjoy the benefit of the premiums. The regular single and club prices of the paper as given on the 2nd cover page, are as low as they can be without diminishing the value of the paper, and lower than they could be were it not for the premiums which increase the circulation. The larger the circulation the greater is the number of persons among whom is divided the general expense of preparing matter, engravings, type-setting, office, etc., and so a far better paper can be given to 100,000 or more subscribers than could be given to a smaller number at the same price per year. Remember that the premiums are paid for out of advertising receipts, which the larger circulation brings in. The extra advertisements on the extra premium supplement will largely swell the list of the premiums. Our friend can shut his eyes on the premium sheet, and read only the regular sheet which, as he says, "is worth what it costs him anyway," and still be satisfied.

**Oats with Wheat.**—The sowing of a bushel of oats per acre, with the winter wheat, has often proved of material benefit to the wheat crop. The oats grow more vigorously than the wheat and aid in catching and holding the snow. The oats act as a protection or mulch to the wheat. The little food the young oat plants draw from the soil is returned during the spring when, being killed by the winter, they rapidly decay.

**Plants, Insects, etc., by Mail.**—We have on hand, at the present time, half a dozen or more packages by mail, containing specimens of plants, insects, etc., sent for us to name, which give no clue to the sender. We have also a number of letters and postal cards, saying in effect, that "a plant or insect is sent this day by mail—What is it?" We are in some cases able to learn who sends the specimen by the hand writing; sometimes a descriptive hint in the letter helps, but after we have done all, there are several left wanting an owner. In the majority of cases the specimen and note can come together under one letter stamp, and it is always better to send thus than to separate them. Where the size of the specimen makes it desirable to send it at the lower rate of postage, then the letter should so describe the parcel that we can be sure to refer it to the proper owner.

**The Farmer's Weather Case.**—In answer to a number of letters asking how, when and where the Weather Case, described in the June number, page 231, can be had, we will say that an official letter from Washington on this point states: "Due notice will be given the public through the press at such time as arrangements for the instruments may be completed."

**A Dairy House on a Small Scale.**—"D. G. C., "Prince George's Co., Maryland, writes: "My wife wants a dairy house, and unfortunately I have neither a spring nor a running stream available, sufficiently near the dwelling house for her purposes; I have, however a very fine well of water, which I have thought could be utilized. My idea is, to dig a pit, say four or five feet deep, wall it up to about four feet above the ground (of course have the pit well drained) cover it with an arched roof, and the whole covered with dirt and sodded. Internally, I would connect the receptacles for the milk and cream, and butter, with the pump in the well, so that whenever the pump is used there would be a flow of water into them. I would be obliged to you for your advice as to the practicability of this plan, and whatever suggestions you may deem advisable to render it successful."—Your plan is a very good one—but you want to have both light and ventilation, by which we mean neither a glare of sunshine nor a breeze, but light enough to see every thing clearly, and a constant change of air. If the water can be held at a temperature at or near 55° you can employ deep setting—otherwise experience teaches some system of shallow setting will be best.

**Amount of Seed.**—There is no precise amount of wheat to be sown per acre—no rigid, inflexible rule to be followed any more than in the application of manure or an artificial fertilizer. Much depends upon the soil; if it be rich, deep, and clean of weeds, the amount of seed need not be great. Mr. Mechi, of England, advocates thin sowing, he using only three pecks per acre; but his land is in high culture, thoroughly drained and clean of all weeds, and every grain strikes its roots deep

into the soil, finds an abundance of food, tillers freely, and soon covers the ground with a vigorous growth. There is much difference in the size of the grains of different varieties of wheat, therefore, the smaller the grain the greater the number of plants that may grow from a given amount. The end to be gained is to have the ground well covered with deep rooted, well fed, and therefore, vigorous plants, and any more or less seed than will do this is a poor seeding. It is evident that we can not give any rule for everybody to follow on any kind of soil under any circumstances.

**"Clydesdales for America."**—The "North British Agriculturist" (Edinburgh), under this head describes three fine Clydesdale stallions recently shipped to the United States. They are of the famed "Prince of Wales" breed, with noted animals as their ancestors. "These horses are only two years old and should prove a real acquisition to the already large number of good Clydesdales in America."

**Implements in the Field.**—One in riding through the country is surprised at the manner in which farmers leave their valuable farm machinery in the field without any protection from the rain and the sun. A shed of rough boards costs but little, and will pay a large interest on the investment, if used to shelter these machines. Because we do not see the slow decay, we are apt to forget that it is going on, until reminded by some costly machine which goes to pieces just at the moment when most needed. This treatment of machines is excellent for the manufacturers, but it is one of the prominent reasons why "farming don't pay."

**Fast Time.**—The remarkable trotting speed of a mile in 2.13½, made by Mr. W. H. Vanderbilt's six-year-old mare "Maud S.," at the Chicago Trotting Park, last month, leads one naturally to look into the character of her ancestors, in order to account for her wonderful performance. Her sire was "Harold" (son of "Rysdyk's Hambletonian" and "Enchantress" by "Old Abdallah." Her dam was "Helen Russell" by "Pilot," son of "Pacing Pilot"; her third dam was "Maria Russell," by Thornton's "Rattler.") It will thus be seen that "Maud S." is from fast stock and a good record might be expected of her. "Her legs and feet are faultless in form, and apparently of a quality that will stand up under any amount of use; and, judging from her actions on the track, she is as faultless in disposition as in conformation." This simply shows that breeding will tell, and that there is a great deal in pedigrees, if made with some definite end in view. "Like produces like."

**Old Meadows** may be quickly renovated by cutting up what may be left of the old sod, with a disk harrow, then applying a good coat of fine manure and seeding with timothy and clover. The surface may be rolled after the grass seed is sown to make the surface smooth for the mower. A good mixture of seeds for meadow hay is Orchard-grass and Kentucky Blue-grass, one bushel each, and six pounds of Red Clover.

**Rain Water from Barns.**—With cave-troughs upon the barns and a cistern, a good supply of water might be secured to supply the stock when the barn well fails, as it frequently does in the summer. The annoyance of dripping eaves and a sloppy barn-yard, with its waste of manure from washing would be avoided, which, aside from saving the water, would more than pay for the expense of cave-troughs and the cistern.

**Muck.**—"R. B. K., "Columbus, Wis. The specimen sent is muck of a very pure quality. It looks as if it might be used as fuel, if taken out in blocks and dried; at any rate, the experiment can be easily made. If dug out at the approach of winter and allowed to freeze, it would be useful as an absorbent in the stables, or it may be added to the manure heap. Having drained it, you can, no doubt, make it raise something better than "wire grass." We should sow Timothy next spring.

**The Grain Weevil.**—"H. J. R., "New Market, Va. The heating of the wheat has nothing to do with the occurrence of the weevil. Just how the weevil first gets into the granary would be difficult to say. It, no doubt, can fly for considerable distances, and may be brought on to the farm in various ways. It comes from no other insect. The perfect insect, or weevil, deposits her egg either upon or in a minute hole she makes in the grain. The egg soon hatches, and the resulting maggot feeds on the contents of the grain; by the time it has made its growth, it has devoured the flour of the grain; it then enters the pupa or dormant state, and in about six or seven weeks from the time the egg was laid it comes out a perfect weevil, ready to continue its kind. How long the insect lives is not exactly known, but it remains over from one crop of wheat to another, in the hostile state, hidden away in cracks and other places of shelter. The best method of getting rid of the weevil, when it has

once established itself, is to store the wheat elsewhere for two years, thus starving it out. To keep the weevils out, the French line their granaries with sheet iron, taking care that the door closes with a tight joint, and covering the ventilating openings with wire gauze.

**Kentucky Blue-Grass.**—Prof. Asa Gray writes: A correspondent wants to know, and asks us to tell him "botanically," whether "Kentucky Blue-Grass," (*Poa pratensis*) is a native grass in that State and Indiana, or whether it was introduced from the East. That is just what I would like to know myself. I do not know of its being really native anywhere so far south as Kentucky. But where did the name originate? "Blue-Grass" is not the English name of any grass, and I never heard it used in New England or New York. If the name grew up in Kentucky it would more likely be applied to a native grass than to any one introduced, which would come with a name of its own. Then is there any blueness about *Poa pratensis*? The insignificant *Poa compressa*, which may be called *Flat Grass*, is bluish; and was not that what was first called Blue-Grass? Somebody may know. [*Poa compressa* is often called "Wire-Grass." Ed.]

**The Cotton Worm Investigation.**—Prof. C. V. Riley, Chief of the United States Entomological Commission, has charge of the investigations of the Cotton Worm, so destructive in the South. For this important work a corps of assistants has been employed, and the members are to be distributed as follows: Prof. J. P. Steele, of Mobile, will go to Texas, and make his headquarters somewhere in the Colorado Bottom; Prof. W. S. Barnard, of Cornell University, will be stationed at Vidalia, La., so as to study those portions of Louisiana and Mississippi omitted in 1878 and 1879, on account of yellow fever. Prof. W. R. Jones, of the Mississippi University, will represent the investigating committee among the cotton lands of that State. Judge J. F. Bailey will have charge of Alabama. Prof. W. G. Farlow, of Harvard University, will aid in experiments to test the usefulness of fungus germs in the destruction of the cotton worm. Some time in September Prof. Riley expects to go to California to take steps towards the cultivation of the *Pyrethrum*, a plant which he believes to be the future, dangerless antidote for the cotton worm.

**Petroleum to Preserve Wood.**—The primary cause of decay in wood is the fermentation and decomposition of the sap that is within the pores. Wood, pure and by itself, is not easily destroyed by the ordinary agencies of nature, namely: wet and dry weather, heat and cold, etc. If the sap within the pores can be either removed or rendered inactive, the wood may be preserved. There are several methods of doing this, such as saturating the wood with mineral salts, creosote, etc. The cheapest, easiest, and therefore the best method, seems to be to charge the wood with crude petroleum. Pine, for example, is made almost water-proof by saturating it with this material, and therefore made much more lasting. Crude petroleum is very cheap, and may be applied with a brush until the wood will take up no more. In the application, care should be taken to avoid accidents from fire, and not approach the work with a flame until it is dry. An application of petroleum is especially valuable to much exposed wood-work, as, for example, the shingles on buildings, which by actual experience are found to be rendered much more durable.

**Grapes from Texas.**—On July 7th, D. M. Perl sent from his "Hungarian Vineyard," in Harris Co., Texas, specimens of European grapes raised in the open air. These were Black Hamburg and Pinot, a white Hungarian variety. He also sent photographs of other varieties that ripen in June, and stated that his crop began to ripen on the last of May. Texas is indeed a favored climate if European grapes can be grown in the open air. The specimens, especially the Hamburg, were well ripened, and of much better flavor than those raised under glass. The bunches were too compact for the berries to be evenly colored, a difficulty easily remedied by thinning. We shall be glad to hear that the present success is continuous, and that these varieties can be depended upon to produce and ripen in this manner year after year, as it opens up a new supply of grapes.

**Norman and Percheron Horses.**—Mr. M. W. Dunham, of Illinois, landed 97 French breeding horses from the Steamer "Egypt," which arrived on the 8th, and were shipped West early in the same week. There were some 30 stallions, 30 mares, and 30 weanlings and sucklings, of which a large proportion appeared to be mares. There were comparatively few grays, but nearly all the importation were very dark, many blacks, with a few bays. It is the largest importation of breeding horses that has ever been made to this country. Several of the stallions were of enormous size, and of the Norman type, others possessed characteristics of the Percheron type. The quality on an average very good.

"Subscriber" has a tree which bears an abundance of fruit somewhat like a small red plum. He takes the trouble to get a specimen, put it in a parcel and send it to this office. With the parcel is a note which shows that the writer wishes to know "all the particulars" concerning the fruit, and whether there is "anything injurious" about it. But the note comes with nothing to indicate where the writer lives, or who he is—he is merely "Subscriber." Such things are very trying to the patience. Any information we may have is always at the service of our friends. As it is of no interest to any one but "Subscriber" to know what his tree is, we can not take up space in the paper to give it. All we can do is to wait until we learn how to communicate with "Subscriber."

**Our Meat Supply.**—Mr. J. Howard, M. P., made the following statement before a select committee of the House of Commons upon the meat supply for the English market: "The live stock of a country can not be increased at pleasure as some previous witnesses seem to imagine....The agency of mothers is indispensable in bringing animals into the world, and these cannot be increased at will. I can build a fresh wing to my factory, but if I wish to increase the number of my animals upon my farm, independently of the question of capital, it is a slow process....Although there can be no question that the vast fields of America are capable of sustaining, perhaps tenfold more cattle than are at present possessed, it is obvious that considerable time must elapse before the breeding facilities of the country can be materially increased." In view of such a statement made by an Englishman, and the fact that London is our great foreign meat market, it is to our interest to increase the number of our breeding animals, in the great West, as rapidly as possible. To send heifers and young cows to market, is not to be commended under existing circumstances.

**The Wheat Crop of 1880** will not be far from 480,000,000 bushels, an increase of 30,000,000 bushels over the unprecedented crop of 1879. If 20,000,000 bushels are allowed for increased demand for food and seedling, there will remain for export at least 190,000,000 bushels. The foreign wheat crop is also generally good, though Russia will probably not market as much as last year. A low price for our wheat is inevitable; but this does not mean to us what it does to the English farmer. The London "Telegraph" on this point says: "The low price of wheat in this country while it leaves a good profit to American growers, enables them to deliver grain at Liverpool, at a price lower than the minimum cost of producing wheat in England, and hence it is to be feared that, in spite of the fine prospects, the British farmer has a cruelly hard time in store for him, even if prices fall no lower. That they are likely to fall so low at least, that an American surplus of about 200,000,000 bushels can be marketed abroad, seems plain. The natural result will be a further abandonment of wheat-growing by British farmers, and a greater dependence hereafter upon American supplies." The good wheat crop everywhere is, it seems, working to the advantage of the American grower.

**Spreading Manure.**—From the time the manure is dropped until it is spread upon the land there is a continual loss, by gradual decomposition and washing by rains. When upon the soil this loss is not sustained, as the rains carry the valuable solutions down into the soil, where they are absorbed and retained. It is, therefore, the best practice to spread the manure upon the meadows and plowed land, in fact anywhere that plant food is required, both now and through the winter. There is a saving in labor to draw the manure in winter, when the snow is on, as it is easier to load it upon a sled than a wagon, and the load can be drawn with greater ease.

**A Leading Crop.**—In view of the diversified character of farming and the many kinds of animals, grains, fruits etc., that can be grown, the question naturally presents itself to the farmer: How many kinds of produce can I grow, and with the greatest profit? There are so many things to be taken into consideration, as the kind of soil, distance from market, climate, and not the least, the individual taste of the farmer, that it is often a hard matter to decide upon the crops to be grown. As a general rule, however, it is best to make some one thing a specialty—the one best adapted to the taste of the man and the circumstances with which he is surrounded, and let the other products of the farm cluster around it and play a secondary part. All cannot grow grain, neither can all be sheep raisers, or breeders of swine or cattle. We are not speaking against a mixed husbandry, but against a loose farming without system.

**The Death of M. B. Bateham**, occurred at his residence, at Painesville, O., on the 5th of August last. Mr. B. was at the time of his death, as he had been for many years, Secretary of the Ohio State Horticultural Society, and was one of the most widely known horticulturists of the country. He wrote frequently for the press, and if we mistake not at one time occupied an

editorial position. We have no particulars of his death, the mere announcement of its occurrence having been sent by a member of the family. Mr. B. was an active member of the American Pomological Society, and the members of that body, as well as a large circle of other friends, will kindly remember him as a genial gentleman and an accomplished horticulturist of wide experience.

**Horses Feet.**—Long exposure to wet and mud at this time of year frequently produces cracks and other troubles in horses feet. The prevention is in keeping the feet clean by frequent washing and wiping dry with a coarse cloth. A little crude petroleum applied to the feet before the horses are taken from the stable will help greatly in preventing them from becoming cracked. If the feet are already in bad shape they should be bandaged and the horse kept where it is dry. Cleanliness is the most effective prevention of troubles with the horses feet.

### Sundry Humbugs.

Correspondents are often surprised when we tell them that we know nothing of, or never before heard of, some party about whom they have inquired. Our friends have seen in far-off country papers, flourishing advertisements, accompanied by pictures, representing what claims to be the advertisers' "Emporium," or "Manufactory," or "Hospital," as the case may be, located somewhere in New York City. So great are the pretensions of these advertisements, published at a distance, that it is not strange that those who do not know the facts of the case, think that the party must be, with such an immense establishment, a well-known and distinguished man. The "doctor" who goes about the country as "Doctor A.," from the "Dispensary" or "Hospital of Doctors A. & B.," or from some kind of a "University," will give a picture of the building, and sometimes locate it by street and number. Other chaps, who advertise remarkable jewelry, sometimes picture their store as an immense affair, and usually on a corner. If those who are attracted by these advertisements could accompany us on a search for the place itself, they would be astonished to find the "Silverware Emporium," or "Jewelry Bazar," in a back room up several flights of stairs, in a dingy and obscure building, while a search for a "Hospital" or "University" is quite likely to terminate in a fifth-rate hotel or cheap boarding-house, or wherever the advertiser can receive his letters. A large share of those who advertise so extensively at a distance from the city are unknown in it.

### AN ILLUSTRATED PAPER

claiming to be published in New York has been advertised, especially in the Southern States, by means of show bills. Large posters 3½ feet, filled with engravings claiming to have appeared in the paper, have been put up in the country post-offices. The price of the paper was \$1 a year, but the first ten subscribers from any post-office would be supplied for 40 cents each. One would suppose that such a discount would of itself excite suspicion, but it appears that a number of Post-masters sent their \$1, but get no papers. As a consequence, letters of inquiry have begun to come to us. The cuts on the poster claimed to have been from last year's issues, and it seemed strange that such a paper could have been issued for a whole year and we had seen or heard nothing about it. As its office was said to be 206 Broadway, we started out to make a neighborly call on such a flourishing contemporary. No. 206 Broadway turned out to be the large and elegant building of the venerable "Evening Post"; inquiry of the janitor and the elevator man failing to give the whereabouts of the "Illustrated News," we went to one of the proprietors, but with a like negative result. Many inquiries for the paper had been made, but no such journal was located there—and probably not anywhere else....Now that the bogus stock brokerage, the "put and call" business has been so thoroughly broken up, the energies of the speculators must find other channels. Some parties have taken up

### GAMBLING ON THE PRICE OF COTTON,

and have sent out their circulars, especially to residents of the Southern States. The story is too long and too complicated to give here, but one by paying the chap at headquarters (he has no office, only a post-office number), the sum of \$2, one can fill out a blank directing the purchase of "a fractional part of one hundred hales of cotton, to be settled for according to the average price for September." The account is very wordy, but it all means betting upon the price of cotton, and all prudent

persons will save their \$2 and let the scheme alone.... A young man who thinks he has been defrauded by a

### "BOOK AND BIBLE COMPANY"

wishes us, If we think the company is a swindling one, to publish his statement. His story is not sufficiently clear, but we can make out from it that he ordered books, not because he wanted them, but because they were apparently cheap, and when they came they had the name of the "Company" pasted over that of the real publisher. If his experience teaches our correspondent and his friends to only buy such books as they need, and to get good, substantial editions, the lesson may not be a dear one....A number of inquiries have been made as to

### A ONE DOLLAR COOKING STOVE,

for which the descriptive circulars make great claims, while they do not show at all clearly where the heat is to come from. One of our associates called to look at the stove, and rendered a written report of his investigations thus: "A cheap frame of tin to set over any lamp. In fact, 'cheap and nasty.'"...There are few subjects about which people in general have less knowledge than they have of electricity, and it has consequently been easy for pretenders to turn it to account in various forms of swindling. In view of the new interest in the subject caused by the more or less successful attempts at lighting by electricity, it is not at all surprising that we should have

### A HUMBUG ELECTRIC LIGHT.

Our attention was called to an advertisement of a Chicago dealer, which was made conspicuous by the engraving here reproduced. The advertisement, after some remarks upon the electric light and its inventors, says: "But it remained for Mr. Krauss, of London, England, to accomplish the desired result. This cut accurately represents his wonderful lamp. It will produce instantaneously an Electric Light of great steadiness and intense brilliancy! Its action being automatic, it requires no attention, and will burn for hours, costing a trifle only. It is adjusted ready for immediate use, and is so simple a child can work it. Price, complete, only \$1. Every lamp is warranted, and is imported." The italics are the same as in the advertisement. Of course we knew that no lamp like that in the engraving could possibly be made that would of itself produce a brilliant light, and wishing to see "the point" of the swindle, we requested a friend in Chicago to invest \$1 for us in what the advertisement properly calls

### A "WONDERFUL LAMP."

The lamp came in due time, and consists of a glass shade upon a base, as shown in the engraving, with wires and carbon points within. The glass is 6 inches high, 2 inches in diameter, and the parts are put together in the most rude and bungling manner. The fraud in this case consists in not telling the whole story. One unfamiliar with electrical matters would suppose from the advertisement, and its wording would warrant him in doing so, that the lamp was complete in itself. But after purchasing the lamp, he would learn from the circulars accompanying it that he would be obliged to either purchase or make a battery in order to work it. The English maker offers batteries ready made, and he kindly shows how to make one from materials he has for sale. One of the circulars says: "Should it happen that any foolish individual has purchased the lamp with the idea

that immediately he takes it from the box it will commence throwing out a bright light forever more, he will even now be enabled to correct his mistake, and construct a battery, etc." That is cool, indeed! The whole object of the advertisement is to convey the idea that the lamp is complete in itself, and then to call the person who gets deceived by it "foolish," adds impudence to rascality. The thing claims to be made by a "Scientific Toy and General Novelty Co.," of London, and in enumerating the various articles it deals in, among "Mechanical Models," "Parlor Fireworks," etc., it offers "Sundry Practical Jokes," we judge that the electrical lamp comes under the head of "Practical Jokes.".... There seems to be a strange lack of knowledge in regard to

### MEDICAL MATTERS.

For example, a correspondent in Nebraska inquires about a "Doctor" who "guarantees to cure epilepsy," asking if he is "reliable," etc. If our friend, evidently a man of intelligence, would think of the matter a minute he could answer the question himself. The very fact that the chap "guarantees to cure" anything, shows him to be a quack to be avoided. A regularly educated and conscientious physician has no such assurance—he knows that he can not "warrant" a cure in any case; at

most he will give his opinion of the probabilities; he is too honest to "guarantee" to do what he knows to be beyond his powers. We sometimes wonder if people remember what they read. Here is a letter from Toronto, Canada, inclosing a circular about which the writer is very indignant, as he says it was sent him "by some scoundrel in New York,"—and closes his letter with: "Cannot you ventilate this villain who claims to be both parson and doctor?" Who does the reader suppose we are thus asked to "ventilate"?—None other than our particular pet, Rev. Joseph T. Inman, with his

#### CORASSA COMPOUND RECIPE

One of our "stand bys" for these fifteen years. Other quacks have come and gone, but Joseph is perennial. We have shown the nonsense of his "Corassa" stuff over and over again, so frequently have we been asked about it. It was only in May last that we were driven to showing up the trick again—and now comes our Toronto friend asking if we cannot "ventilate"!!

**Wheat Culture—A New Work.**—In view of the increasing interest in the cultivation of the staple crop—Wheat,—we are glad to announce that the Orange Judd Company have in press, an entirely new work entitled: "Wheat Culture; How to Double the Yield and Increase the Profits." By D. S. Curtiss, Washington, D. C. For many years a Farmer in Michigan, Illinois and Wisconsin. The few existing works on wheat culture, besides being somewhat antiquated, try to tell too much, and while they are useful for reference are quite too bulky for hand-books. The author of the present work, we are informed, has had wide experience in wheat culture, and has put what he has to say in a compact, clear, and practical form, and it cannot fail to meet the wants of a large number of farmers. The work will probably be ready soon after this paper reaches its readers.

(Basket Items continued on page 365.)

#### A Farm Gate.

Mr. "M. H. H.," Luzerne Co., Pa., sends a sketch and description of a gate he has in use, and is so

Fig. 1.—A CHEAP AND HANDY FARM GATE.

cheap and satisfactory that he desires that others may make and use it. The posts are set at the desired distance apart, and a heavy plank, or better, a timber with a smooth upper side, is laid level with the ground between the posts. This makes a track for the wheel, fastened at the lower corner of the gate, figure 1. The gate is made of the same form and of the same material as an ordinary swinging gate, care being taken to fasten the bottom wheel securely to the frame. A strip of board should come down on the outside of the wheel and hold the bolt which passes through it, the wheel, and the gate. A pulley is placed upon the opposite and upper corner, which should be six inches in diameter, and with a deep groove, which prevents the pulley from getting off the upper board of the fence along which it rolls. The axle, figure 2, of the pulley is an iron rod which bends at right angles and passes down the side of the end piece of the gate, to which it is firmly secured by stout nails or screws. Old iron wheels may be often found around the shop to answer the purpose.

Fig. 2.

Old iron wheels may be often found around the shop to answer the purpose.

**Mixed Husbandry** consists in the cultivation of various crops, and keeping of most kinds of do-

mesticated animals,—in short it embraces all of the other systems, but on a smaller scale. It implies a thorough knowledge of animal and vegetable life in all conditions of soil and climate, every aspect of rural economy at home and abroad, and also an acquaintance with the allied arts and sciences. It possesses one prominent advantage over the other systems, and that is its freedom from risk, and sure returns for money invested. If one crop is a failure, another may be unexceptionally good; if pork is low, beef and wool may be high; if fruit is abundant and cheap, vegetables may be scarce and dear. Though mixed husbandry is seldom characterized by as large profits as in grain or pastoral farming, it is not subject to such severe losses by storms and bad weather. If the farm is well stocked and cultivated, it will be continually undergoing improvement, and instead of becoming exhausted, will get more and more productive.

ONTARIO.

#### Preventing Collar-Galls.

Having been considerably annoyed by the continued galling of horses' shoulders by the collar, the writer took time to investigate the subject. It was found that the whole trouble arose from the direction of the draft causing unequal pressure on the shoulder, which operated differently upon differently formed horses. The collars being similar in form and size, and the line of draft of the harness being the same, the shape and inclination of the shoulder, the height of the horse, the width of the chest, and other variations, caused an inequality in the pressure, which acted so as to gall the shoulder. Pads upon the collar were unsatisfactory and only temporary expedients, but nevertheless they were very useful when properly

Fig. 1.

made and fitted. The best results were reached by using adjustable attachments to the hames for hooking the traces, so as to change the line of draft, to suit the angle of the shoulder, by raising or lowering the position of the trace hook on the hame. The arrangement is shown at figure 1. It is made of an iron plate, with a number of holes in which a hook or link can be fitted, so as to raise or lower the draft, and change the line of pressure of the collar on the shoulder proportionately. The action of the arrangement can be seen as soon as the horse pulls on the trace, and if it is not precisely correct, should be changed until it is, and the line of pressure brought parallel with the line of the shoulder. To protect a galled shoulder while it is healing, pads of the form shown at figures 2 and 3 may be used. These are made of stout canvas and filled solidly with tow or hemp; a covering of smooth, hard leather may be added. Straps and buckles are used to fasten them to the collar. The pad is fitted to the col-

Fig. 2.—A COLLAR PAD.

Fig. 3.—ANOTHER FORM.

lar in such a manner as to relieve the galled part from pressure; and either kind of pad will be found useful for different kinds of galls.

#### Cement: How to Mix.

Inquiries by letter in regard to the various details of cement, its composition, methods of mixing it, etc., are quite frequent and we make a general reply. Cement is made from what is known as Hydraulic Limestone, that is, a rock which, besides Carbonate of Lime, contains a considerable portion of Magnesia, Silica, and Alumina or Clay. The Rosendale cement, the leading kind in this country, and nearly as good as the imported Portland cement, is manufactured at Kingston on the Hudson, N. Y. The composition of this Kingston rock is as follows: Carbonic Acid 34.20; Lime 25.50; Magnesia 12.35; Silica 15.37; Clay 9.13, and Pe-

roxide of Iron 2.25—the latter being of no value. Pure lime-stone is made up entirely of the first two substances in the proportion of, Carbonic Acid 56 parts, and Lime 44. Such a stone, when burned, loses the carbonic acid which passes off as a gas and pure quick lime is left behind. When this quick lime is brought in contact with water, a combination takes place, heat is evolved, and hydrate of lime is formed—this process is called slaking. When the water is in just the right proportion to slake the lime, a dry white powder results; if the water is in excess a paste of lime is formed, and is the substance which builders mix with sand to make mortar. When clay is present, as in the case of the Kingston stone, the burning gives, instead of quicklime, a hydraulic lime, which combines with a much larger per cent of water, and instead of falling to a fine powder sets into a stone again. This setting into a stone takes place even in excess of water, because only a definite amount enters into the combination and the remainder is excluded. The hardening will therefore take place under water, and this is the most valuable property of the cement. When this cement is made into a thin paste and mixed with gravel or poured over broken stone, a concrete is formed which soon hardens into a mass with the firmness and durability of stone. The setting takes place quite rapidly, which makes it necessary that the cement be used, that is, put where it is to remain, very soon after it has been mixed with the water. The method of using cement is therefore quite different from that of mortar. The cement and sand—if sand is used—should be thoroughly mixed together while dry, and in the proportion of four parts of sand to one of cement, after which the water is added, and when a uniform paste is obtained, it should go at once to its place of hardening in the wall, etc.

#### Editorial Correspondence.—Items from "Notes by the Way."

[Owing to the extra printing required by the Supplement, this number goes to press early, and Mr. Judd's "Notes and Observations at the West" have not come to hand as we close these pages, except the few items which we give below.—Eds.]

##### Quick Crops from Prairie Soil.

We are now passing over broad prairies, still unbroken by the plow, except here and there where the new comers have built "sod cottages," and turned over a few acres on which are corn-stalks struggling for existence. As a rule with those who settle on prairie lands—as hundreds of thousands have done, during a year past, and as multitudes are now doing every month—the sod is broken the first year, allowed to decay until the following spring, before a crop of corn or spring wheat is put in. It is an immense gain, for emigrants from the Eastern States and from Europe who come hither early in spring, to put in a crop at once that will furnish food for the following winter. There is no doubt that this can be done much more largely than has been generally supposed. We have seen to-day and yesterday, fair corn, pretty good oats, promising potatoes and beans, all on ground that in April last, was in its wild state. The corn and oats are on sod treated thus: First a team with the usual breaking plow goes ahead, and a thin sod two to three inches deep is turned over flat. Following immediately after is another common plow, set to cut one to one and a half inch deep, which takes up a second layer of the under soil and throws it upon the turned sod. A light harrow, with the teeth inclined backward is then put on which finely pulverizes the top layer and a little of the soil on the sod, but without tearing up or disturbing the sod itself. This furnishes a good seed bed in which the corn is planted, and the oats sown. They keep ahead of the weeds, and show well at this date.

##### Potatoes in Fresh Prairie Sod.

We saw in one place about half a dozen acres in potatoes planted thus: The plow turned the sod over about three inches deep. A boy followed the plow and against the edge of the turned fur-

row placed a cut piece of potato, or a small one whole, once in every three feet or so. The next furrow covered them, and in due time they sent up a good growth of vines between the sods. The vines look very thrifty, and on opening a few places we found a plenty of growing potatoes, some of them large enough to cook to-day (Aug. 9), and all promising a good crop. In another place the plowing was first done, the sod opened with a sort of wooden spud, the potatoes dropped in, and the opening closed by drawing in a little soil with a hoe. For some reason this plot did not look so well as the other, but it may have been due to other causes than the mode of planting. The first method required the least work. The latter may be preferable when not ready to plant at the time of breaking up of the prairie sod.

#### Field Beans on Fresh Prairie.

We have also seen very good crops of field beans growing on land broken the present year. These were planted in the cracks between the turned sods, in some cases by sticking them in by hand, and in others by forming a receptacle  $1\frac{1}{2}$  to 2 inches deep with a wooden implement like a crowbar, with the end flattened out to an inch in thickness, and three or four inches wide, and blunt at the bottom end. A cross pin through it regulated the depth. The holes were made with a single thrust, the seed dropped, a little dirt thrown in, and the work was done. Another plan is to use an old axe, which is struck down between sods, or into them, the seed, corn or beans, dropped in, two blows struck on each side to loosen a bit of the soil, which is pressed down with the foot to cover the seed. These beans, as well as the potatoes and corn above described, will supply excellent nourishing food for man or beast during the coming winter.

White turnips on prairie sod can be grown with fair success, not always with certainty, as in a dry season they may not take, or may dry out after they have made a good start. They can be put on any broken sod, harrowed, and sown during July.

#### A Yorkshire Man on a Prairie Farm.

By an incident of travel, we chanced upon a large prairie farm in Leyden Township, Illinois, and had a familiar chat with the owner, Freyer Marwood. He came from Yorkshire, England, direct to the West, and had but a single dollar left in his pocket on arriving upon the western shore of Lake Michigan. To-day (Aug. 9) we found him with his three sons on a farm of about 600 acres, all purchased at from \$50 to \$100 per acre, and paid for out of the products of the farm itself, and he now lives in a fine residence recently erected. Some items from his experience will be interesting to many young men in the Eastern States, as well as to multitudes in his native country. They may also well be studied and *thought about* by not a few of the older and more recent settlers upon prairie farms over much of the West. By the way, Mr. Marwood says that while young men from crowded old England may generally improve their own condition by emigrating hither, and leave more room and scope for those remaining behind, he strongly advises the older people not to come. Those having their modes of thought and work fixed by years can not easily adapt themselves to the habits of this new country. They will always be longing for the fatherland, be uneasy, and have no certainty of success. When he came he resolved to at once

#### Become an American Citizen,

and adapt himself to the country he had chosen for his future home. He registered immediately, and felt himself to be henceforth a full-blooded American, and determined to make the best of it. Having learned the blacksmith's trade in youth, he worked at this until he acquired a few dollars capital. In 1857 he rented 40 acres, with a small house on it, at \$70 a year; raised what corn, potatoes and oats he could, and after nearly five years had only a small stock of cows left. In 1861, having learned the way to work, he rented another farm of 160 acres at \$300 a year, and went to raising corn, oats, grass, and some wheat. At the end of four years he had by strict economy, and hard work paid the rent and saved \$2,000, with some stock and implements. In the year 1865 he made

#### His First Purchase of Land,

a farm of 120 acres, at \$50 per acre (\$6,000), paying down his \$2,000, and having six years to pay the balance of \$4,000. This mortgage he paid off in less than four years out of the products of the farm. It should be stated that in all these years he cut more or less grass from the unoccupied prairies around him—an opportunity not now open anywhere near any city or village. During the past 11 years he has invested the profits of the farm, not in bonds and mortgages, but in improving the farm itself, and then in buying adjoining land of less practical neighbors, and putting that into a condition for profitable culture. He regards the land as a *machine* for producing crops, and for it to do its work profitably it must be kept in the best condition, and he furnished with the necessary materials out of which to make crops.

#### Using Much Manure on Prairie Soils.

He ridicules the common practice of burning straw from new prairie land "to get rid of it." On the contrary, he has from the first saved and worked into manure every forkful of straw not eaten by the stock, when he could not sell it at good prices to villagers or city dealers who keep horses. The teams carrying the straw to market always bring back a load of manure. Though his land is as fertile as the average of new prairie, he finds it pays to put on all the manure he can make and get. His large crops of corn, oats, and grass, prove he is correct, as does the constant improvement in yield, instead of the usual depreciation after a few years of culture. Two tons per acre of good Timothy, 70 bushels of oats, 60 to 70 bushels of sound corn are other evidences. But this is not all.

#### Another Secret of Success

is his belief that he *owns all the soil under him*, and that some of it can be turned to account. After the first thin breaking and rotting of the tough sod, he puts the plow right down from 12 to 18 inches deep, and brings up the buried stores of fertility. He plows the manure down to the bottom, thus tempting the roots of plants to go down there, where they find not only food, but moisture and coolness even in the driest hot season. The great multitude of prairie farmers who burn their straw, and claim that three or four-inch deep culture is ample, may well take a hint from Mr. Marwood's successful experience. Facts tell stronger than theories or whims. The leaven of English ideas about deep plowing and heavy manuring is not bad, even for slipshod prairie farming.

#### Other Items.

After breaking the sod one season, and allowing it to rot until spring, Mr. M. usually sows flax as a first crop, especially as it is one that requires little labor. This is cut with the mowing machine, and run through the thresher, and yields 12 to 14 bushels of seed per acre, which seldom sells below \$1.30 per bushel, and often higher. Some of the straw is frequently sold at \$3 to \$4 per ton, only about paying for hauling it to the mill. As it is of little value in itself for manure, it is usually put at the bottom of the yard as an absorbent of the liquid, and ultimately mixed with the whole of the manure. Flax after flax does not do well. Oats or corn generally follow the first flax crop. Oats do not follow oats well. Corn may follow corn year after year, on good prairie soil, and for an almost unlimited period if the manure is saved and applied on such soils. Poor to medium or fair crops of corn may be grown for several years on ordinary prairie land, but large, paying crops are the rule on land frequently manured. The plowing, the culture, the seed, etc., are the same for a poor as for a good crop; the actual cost of applying the manure is repaid several fold.

[The latest from Mr. Judd is a dispatch stating that he was (Aug. 12th) on his way to Bismarck. He says:] I met with many intelligent farmers in Wisconsin and Minnesota, and examined crops in both those States. Farmers are in excellent spirits, as they well may be, with dairying generally good, and crops of corn everywhere superb. In Wisconsin, wheat is somewhat below the average, while in Minnesota it is above. In the southeast,

some damage from the chinch-bug is reported, but in the northeast, the crop is unusually fine, and the harvest weather is all that could be desired. After studying the most recent official county reports, we estimate the crop at forty-eight millions of bushels, which is an increase over former crops of nearly one-half. We find both Americans and foreigners are settling upon the Northern Pacific R. R. lands, the foreigners probably predominating. I met with an intelligent Englishman who had just come over with twelve children. At home he had been a large tenant farmer of the better class, having paid \$4,000 rental annually. Here this sum will purchase outright more land than he hired at home. We do not wonder that he reports that many of his neighbors similarly situated are coming.

#### Stable Rake and Scraper.

A handy combination rake and scraper for the stable can be made as follows: Select a hard-wood stick, fifteen inches in length, four inches wide, and an inch and a half thick; bring it to a triangular shape in cross-section by shaving down one

STABLE RAKE AND SCRAPER.

side to a thin edge. Bore six or eight  $\frac{1}{2}$ -inch holes into the unshaved side, to the depth of two inches, and insert in them sharpened hard-wood pins, that will project three or four inches. A handle, of the desired length, is then made and inserted, and braced, as shown in the accompanying engraving. Such a tool may be used to either push or pull the litter and manure, the toothed side being especially adapted to loosening and moving those portions that the smooth side will not catch.

#### Swamp Muck—Its Value.

An item some months ago to the effect that it had been shown that an acre of swamp muck was worth \$25,000, has called out several inquiries. This item referred to a former article, and it should have explained that analysis shows that some muck is rich in fertilizing constituents, so much so that at the usual prices of nitrogen, etc., an acre of the muck *three feet deep* had been estimated to be worth the sum named. Very few have an idea of how much of a pile an acre to the depth of three feet would make. The chemist may show that muck contains certain fertilizing materials, yet that may be in an unavailable form, for the plant does not always find and take out what analysis shows a soil to contain, just as the working of a gold or silver mine never turns out anything like the amount of metal that an assay shows to be in the ore. Muck, as to its agricultural value, has been both much underrated and greatly overestimated. There is muck and muck, and it varies so greatly in different localities that to speak of it as something of uniform composition, like plaster, for example, is liable to mislead. While a given deposit of muck may contain all the elements of fertility, these may not be in a condition to be available as plant food, and may even be the case that they are in a form that would be injurious to vegetation were fresh muck to be applied as a fertilizer. Fresh muck applied to land is of little or no use. If dug in the spring and spread, it dries into hard lumps, and we have known them to retain their form the whole season. For muck to be useful at all, it must first be brought into proper mechanical conditions. It should be dug in fall or early winter, so that the frosts may break it up and thoroughly pulverize it. When in the proper condition, and both fine and dry, it may often be used to advantage in stables as an absorbent of liquid manure. We say "often," as it may happen that leaves or sawdust may be had for hedding at much less than it would cost to get out and prepare the muck for the purpose. Each case must be con-

sidered by itself, as what would be a profitable course for one might be the reverse for another. One may have a deposit of muck under conditions which would make it improper to dig and remove it, and the best economy would be to leave it where it is. If, for example, there is a deposit of muck in a low place, which can not be drained for want of sufficient out-fall. If the muck is removed from this there will be large open pits or ditches; these, if left, will become pools of stagnant water, sure to be unsightly, and often unhealthy. It is true, these may be filled up, but the labor required would probably more than counterbalance any benefits that might come from the use of the muck as an absorbent or a fertilizer. It often occurs that the best use of a deposit of muck is not to remove it, but to cultivate and improve it; if it can be done, drain it thoroughly, and it may often be made the most valuable meadow upon the farm. In the opinion of those who have had the widest experience in the use of muck, this is in many cases the best use to make of a deposit. Our point is, that with muck deposits, as with many other things in agriculture, there is no one rule to meet all cases. While it may be best for A. to dig his muck and let it find its way to the manure heap, such a course, if followed by his neighbor B., would, to use an old expression, "cost more than it came to."

### The Preservation of Corn Fodder in Silos.

In an article with this heading last month, the principle upon which corn fodder and other green fodder is preserved by *ensilage* was described. It is, in brief, to cut the fodder as fine as may be, to store it in air-tight tanks or silos as compactly as possible, and to cover it as closely as practicable; all the preparation in the way of structures and every operation in filling them having for its object the most thorough exclusion of the air. To those who would investigate the matter in full, we give the following references to the literature of the subject, from which it will be seen that it should be no novelty to the readers of the *American Agriculturist*. Though there had been previous references to what is known in Germany as "sour keep," in which clover, beet leaves, etc., were preserved, the first important article we now remember was on "Sour Fodder Making," by a Hungarian correspondent, published in October, 1873, p. 370. This described, with an illustration, the method of cultivating fodder corn and storing it in pits or ditches, as practised in Hungary, and does not require a building expressly for the purpose. In August, 1874, p. 297, we gave, from the same correspondent, "Sour Fodder Making in Hungary." This described the Hungarian method of storing beets and other roots, previously cut, with chaff in pits or stacks partly below ground and covered with straw and earth, with an engraving showing a pit.

In April, 1875, pages 139-40, we gave an illustrated description of "A Dairy Barn" in Westchester County, N. Y., in which an account was given of a pit for the storage of brewers' grains. Several thousand bushels of grains were kept in good condition for months, simply by excluding the air.

About this time the preservation of green fodder attracted much attention in Belgium and France, and several articles by farmers and professors in agricultural schools appeared in the *Journal d'Agriculture Pratique* (Paris, the leading agricultural journal of France), giving methods and reporting general success. The important portions of these articles were presented in a condensed form in the *American Agriculturist* for June, 1875, pages 222-223, with six illustrations showing simple pits and extensive receptacles for the fodder built entirely above ground, with the method of filling, etc.

In September, 1877, pages 335-336, we described "An American Silo." This gave two illustrations of the pit attached to the Westchester Co., N. Y., barn (described in April, '75), with hints as to the utilization of such pits for the storing of corn fodder.

In 1877 Mr. Auguste Goffart, an eminent French agriculturist, published at Paris a work on "Ensilage." This was translated by J. B. Brown, of New York, and published in 1879. Besides Goffart's original work, this had an appendix giving

several other articles and notes by that author and several of his countrymen, the experience of Francis Morris of Maryland, extracts from the *American Agriculturist*, besides a note giving "Conclusions of the Translator," in which he says: "The first notice of this matter in this country seems to have been made in the *American Agriculturist* of June, 1875." As shown above, Mr. B. was not exactly right as to the date, though quite correct as to the fact. This work was, we believe, published by the "N. Y. Plow Company," in part at least to aid in the sale of the implements made by them for the cultivation and cutting of fodder corn. In April, 1879, we gave an engraving and description of the "Ensilage Cutter," and in July of the same year noted that a supplement to Mr. Brown's translation had been published in a pamphlet form.

On July 6th last, Mr. O. B. Potter read before the "Farmers' Club of the American Institute" a paper giving his experience in preserving fodder by ensilage. This appeared in the "N. Y. World" of July 9th. Mr. Potter's address is not given, but we infer that he lives in Westchester, N. Y. Had there been some one present to question the writer upon a few points which need explanation, this would be the most direct, practical, and compact presentation of the subject of ensilage that we have yet seen.

The latest contribution to the literature of the subject has this title: "The Book of Ensilage; or the New Dispensation for Farmers. Experience with Ensilage at 'Winning Farm.' How to produce Milk for one cent per quart; Butter for ten cents per pound; Beef for four cents per pound; Mutton for nothing, if wool is thirty cents per pound. By John M. Bailey, Proprietor of 'Winning Farm,' Billerica, Mass., and 'Virginia Stock Farm,' Sussex Co., Va. Billerica, Mass. Published by the Author. 1880." There are also some quotations on the title page which we omit. Preceding this title page is an advertisement of "Bailey's Practical Tree Trimmer," one of "Mammoth Ensilage Seed Corn," and a portrait of "Yours Respectfully John M. Bailey," and also Mr. Bailey's hat. Of introduction and contents there are 10 pages; to the subject of Ensilage 111 pages are devoted. The Horses, Sheep, Shorthorns, and Swine, for sale by the author are described in 81 pages and 28 pages of "The Book of Ensilage" are occupied by advertisements of animals, fertilizers, implements, etc., offered by other parties. As mutton can be, according to the title page, raised "for nothing" if one gets enough for his wool, so we suppose a book can be published "for nothing," if one can get enough advertisements, at good prices. Less than half of "The Book of Ensilage" is occupied by ensilage, the larger half being an advertising medium.

Having referred the reader to the sources of information, we recapitulate the important points. Our Hungarian friend described a pit dug in dry soil, 12 feet deep, 12 feet wide at top, 6 feet at bottom, and as long as need be (10 to 20 rods); he stated that this might be walled if stone or brick could be obtained cheaply, but that this was not necessary. Later writers prefer to make the pits wholly, or in part, above ground, and advise them to be carefully walled with brick, stones, or concrete. Some French pits built quite underground, and lined with masonry, are 9 feet wide above, 6 feet below, 6 feet deep, and 75 feet long. Goffart built some of his silos entirely above ground, but, on the whole, prefers to have them one-half their height below ground, and this is the plan generally preferred. According to Bailey, a silo 12 feet high and wide, and 30 feet long, will hold 80 to 100 tons of fodder, or enough to winter 12 to 15 cows. The walls should be thick enough to resist the pressure of the earth without, and those above ground, the pressure from within; where concrete is used, they should be 15 inches thick. As the fodder soon wilts and occupies less space than before the mass settles, it is desirable that there should be nothing in the shape of the pit, or the character of the interior surface of the walls, to prevent the mass from settling evenly and becoming compact and solid throughout. A suitable roof is needed to shed rain. The cutter should cut the corn into half-inch lengths or smaller, and be run by steam

or horse power. The fodder corn should be cut at the time it is in its best condition for feeding, i. e., when the "silk" first appears. The cut fodder is trampled down as close as possible, and during the intervals of the work of filling, planks should be put on the top upon which weights are placed.

Formerly a portion of straw was put with the corn fodder, but this is not now regarded as necessary or even desirable; neither is salt needed to preserve the fodder, though sufficient may be added to make the food palatable to the animals.

The pits or silos are not filled at once; after what may be cut in a day, or enough to fill the pit to the depth of about two feet, has been put in, it is allowed to remain for about 36 hours, is then thoroughly trodden down, and a similar deposit of freshly-cut fodder placed upon it, and so on.

Great importance is attached to the proper closing up when the pit is full. The successful keeping of this fodder depends upon exclusion of air.

M. Goffart prefers to cover his by first placing a layer of several inches of straw upon the surface; upon this he puts boards or planks laid crosswise, so that they may be taken out one by one, as the fodder is removed in feeding. The boards should fit closely at their edges, and upon them are to be placed weights to keep up a continuous pressure upon the mass below. For this purpose logs, stones, bricks, or other heavy material may be used, or old bags, or, preferably, boxes filled with earth may be made to serve as weights.

Mr. Potter prefers to cover the fodder first with straw for about two inches, and upon this a layer of clean earth at least six inches deep. After the earth has been in place a week or so, it is examined, and if any cracks are found they are to be closed with fresh earth. This examination should be repeated two or three times. Mr. P. does not find that any other weight beyond that of the earth is necessary, but suggests that should additional pressure be desired, it may be secured by increasing the thickness of the layer of earth.

If pits are made in the open ground, they should be covered with a thick layer of straw and several inches of earth, putting on as much as would be required in the locality for protecting turnips, etc.

We have had special reference to the preservation of fodder corn, but the process is equally applicable to other green fodder crops, such as sorghum, the various millets, etc. Where beets are raised in large quantities their leaves may be preserved, and where cabbages are grown for market there is a large amount of refuse leaves that could be thus put down—indeed the process is really a modification of that for making sour-kraut.

Clover has long been preserved in this manner in Germany. A friend who has seen it fed, describes the clover as coming out as a brown, "cheesy" mass, which has a strong odor of fresh clover, and which the cattle eat with the greatest relish.

Mr. Potter, in the paper referred to, speaks in the highest terms of clover preserved in this manner, and says: "Among all our products in the Northern States there is none that will be more enhanced in value by this system than red clover." He advises the mixing of clover, or grass in which clover predominates, in the same pit with and through the fodder corn. He says: "The clover becomes, after the first fermentation, a putty-like mass, which fills the interstices of the coarser and more fibrous fodder, and thus makes the whole much more compact and weighty than it would otherwise be, while it improves the quality of the food."

In conclusion, we would say that we think that there is sufficient merit in this method of preserving green fodder, to make it worth while for our farmers to look into and experiment with. The trouble with every new thing is that some enthusiast gets hold of and advocates it in an extravagant manner, as the one thing that is to bring in the "good time coming." He finds followers, who abandon the old ways for the new, and not finding the new all that they expected, overlook the real merits it may have, and denounce it as a whole. Our advice is to "go slow." Try every new plan of promise to see how far it may be useful to you; examine its faults as well as its merits. Those leaders who start off with a band of music and a

"hurrah, boys," have their use, but as guides are not so safe as those who work carefully and quietly.

### Apples, Apple Juice, Cider, Vinegar.

This is most emphatically "the bearing year" with apples. Not only are well kept orchards in full bearing, but every superannuated and half-decayed tree, and every scrub and chance seedling by the roadside, is loaded in a manner seldom seen in a lifetime. With this abundance it is evident that with apples there will be a glut in the market. There will be no room except "higher up," and those who send poor fruit to market had better use their barrels for fire-wood, and save the freight charges. There is always a certain demand to be met, but this year only the select fruit will supply it. In years of plenty, careful selection and neat packages tell. The almost daily inquiries as to fruit dryers show that preparations are being made to dry a share of this abundance, and we hope by this article to anticipate the inquiries that will soon be made as to disposing of the fruit in the various liquid forms. Apple juice, as it comes from the press, or "sweet cider," is liked by many, and we have inquiries as to keeping it in the unfermented state. Preserving powders are advertised, and some of these from their effectiveness in preserving fruit will no doubt keep fruit juice equally well. The majority will wish to preserve their sweet cider without addition, and these can treat it by the same method used in canning fruit. Heat the cider to the boiling point, bottle and cork it while still hot. When apple juice is exposed to the air, the natural ferment it contains causes a change to take place. The sugar in the juice is converted into alcohol, and carbonic acid is given off. This process may be carried on until all the sugar is decomposed, when it is "hard" cider. The fermentation may be arrested at the desired point by bottling, and sparkling cider will be the result. This, which is also called "champagne cider," can only be produced by bottling before the fermentation is quite finished. The best still cider is made from late ripening apples, when the weather is cool, fermented slowly at as low a temperature as possible, taking care to exclude the access of air; when fermentation has quite ceased, the cider should be racked off into a clean cask, and kept securely bunged or bottled. The great use of apples in this year will be to make vinegar. In the fermentation of cider, the sugar of the apple juice is converted into alcohol, and in making vinegar, that alcohol is changed into acetic acid. The conditions of this change are full exposure to the air and a high temperature. The richer the cider in alcohol, the stronger will be the vinegar, and the more slowly will the change take place. Ordinarily, the cider is put away in the cellar or some out-building, and in time, it may be two or three years or more, will be found to be changed into vinegar. Those who have heard of the "quick vinegar process," thinking it can be applied to cider; we are often asked to give a description of it. In this process, a liquid containing alcohol, usually in the form of cheap whiskey, is converted into vinegar in a few hours. But this is not applicable to cider, for in the fermentation of cider or other fruit juices, the change into vinegar is accompanied by the growth of a very low form of plant, "the mother," as it is usually called, and this would so clog up the apparatus of the quick method as to very soon put a stop to it. Still, the change of cider may be greatly hastened. Those who make cider vinegar on a large scale have a house especially for the work, and this is heated to about 70°. Vinegar can not be made rapidly at a much lower temperature. Exposure to the air is important, hence the casks are not filled, but only partly so, in order to expose a broad surface of the liquid to the action of the air. Exposure is increased by frequently transferring the cider from one cask to another, letting it run very slowly. Exposure can be promoted by allowing the partly formed vinegar to slowly run down a long trough, and also by allowing it to trickle over corn cobs placed in a cask, the cobs having been previously washed and soaked in good vinegar. Old vinegar acts as a ferment, and hastens

the change, and the mixing of new and partly formed vinegar with a portion of old and strong vinegar helps the change. Another method to hasten vinegar making is to add yeast to cider, or what produces the same effect, the "mother" from vinegar barrels. The conditions for the most rapid conversion of cider into vinegar may be summed up: A temperature of at least 70°, all possible exposure to the air, the addition of old vinegar to the new or the use of "mother." It should be remembered that the weaker the cider in sugar the weaker will be the vinegar, and the more rapid the change.

### A Convenient Fruit Picker.

A leading daily paper, a short time ago, announced that some one had invented an implement for picking fruit, and went on to describe one of the oldest devices for the purpose, as if it were a new invention, and it was no doubt new to that writer. Fruit pickers have long been in use, and the records of the Patent Office will show that a great variety have been invented. Some of them are too complicated to come into general use. A fruit picker is only of use to bring down such fruits as cannot be reached by hand, from a ladder or otherwise, as those that grow in such positions are usually the finest specimens, and too valuable to be shaken off, it is worth while to take some trouble to secure them in a perfect condition. We have shown in a former volume that a fruit picker may be made from an old fruit can; the can, with a V-shaped notch cut in the upper edge, is fastened to a suitable pole, putting a lock of hay, some paper, or other soft material in the can to prevent bruising. By catching the stem in the V-shaped notch, the fruit is readily detached and brought down. But such a picker, though effective, is only a make-shift, and as it has to be lowered to remove each fruit, it makes hard work. A better picker, and one that is quite as good as any, is one invented by Jas. H. Ten Eyck, Auburn, N. Y., who sent the sample from which the engraving was made. It is a bottomless dish, 3 inches high, 5 inches across at the top, and 3½ inches at bottom, made of tin, with a socket to receive a pole of convenient length. Above the edge there project two stout iron wires of the shape seen in the cut; these are close together below and diverge above, and serve as fingers to catch the stem and detach the fruit. The most important portion of the affair is not shown in the engraving; this is a bottomless bag, or hose, of cotton cloth, of the diameter of the bottom of the picker, to which it is attached by means

A FRUIT PICKER.

of a small copper wire; it should be about two feet longer than the pole. If poles of different lengths are used, then the hose may be made longer by having extra pieces to be buttoned together. To use the picker, the pole is held in one hand, while the lower end of the hose is taken in the other, and turned up to about four feet from the bottom, thus forming a loop. A fruit is detached and drops into this looped part of the hose; the next one, if allowed to fall directly against the other, would bruise both; to prevent this, the hose is grasped by the hand that holds its lower end, closing it sufficiently to break the fall, and then releasing the hose to allow the fruit to pass down. When the weight becomes inconvenient, the end of the hose is turned down, and the fruit allowed to slip gently into a basket. Mr. Ten Eyck furnishes the picker complete, except the handle, to those who prefer to buy one rather than make it, but he has not patented it. He writes: "My object in sending it to the *American Agriculturist* is to give every one the privilege of making and using it," thus showing a liberal spirit which his brother fruit-growers will without doubt appreciate.

### What is Founder?

In works on Veterinary Surgery, the trouble popularly known as "Founder" is described as *Laminitis*, or an Inflammation of the Foot. This disease appears in two forms. In the simple form the sensitive lamina of the foot and the equally sensitive sole are affected, while in the more severe form the bones of the foot are also included. Among the many causes of this disease, perhaps the most common is the severe concussion from fast driving on hard roads, over-exertion and over-feeding, and drinking cold water when the horse is heated. The treatment recommended by Dr. Williams, one of the most eminent authorities, consists in the administration of mild purgatives. Tincture of Aconite in small and repeated doses, as a febrifuge, with poultices to the foot in the early stages of the disease and cold applications later. He recommends also the application of Mr. Broad's shoes. Mr. Broad's plan is: "As early as possi-

BROAD'S SHOE FOR FOUNDERED HORSES.

ble, get lightly nailed on the feet affected, extremely stout, wide-webbed and long-bar shoes, made from iron about twice the ordinary thickness that the particular horse's shoes are made from; make them gradually thin from behind the quarters, so that the heel part of the shoes is wide and thin, and fitted rocker fashion, which enables the horse to throw his weight where he tries to, much better than he can in ordinary shoes or without any; that is, off the pedal bone on to the soft elastic tissues and tendon behind it, which are much less vascular and sensitive." Mr. Broad's shoe for foundered horses is shown in the accompanying engraving.

### Success with the Currant Crop.

Our long-time correspondent, "W. C.," who is never led away by enthusiasm, gives us the following bit of experience. We may say that his place is on the Connecticut shore of Long Island Sound, and that his sales were made in one of the many prosperous small towns of that locality:—"I have been experimenting with the currant for the last five years, on a small scale, and the present season have produced 120 quarts on three square rods, and they were sold to a huckster at 12 cents a quart, wholesale. They retailed at 16 cents a quart, delivered in the village. At the wholesale rate, the amount of sales for an acre would be \$768. The varieties were the 'Red Dutch,' 'Versailles,' 'White Grape,' and 'Cherry.' About half of the patch were 'Red Dutch' in full bearing, and the other part in various stages of growth—none of them in full bearing. The rows of plants were four feet apart, and the plants three and a half feet apart in the row. The plot had received a liberal dressing of Canada ashes two years before, which I think one of the best and cheapest fertilizers for all kinds of fruit. It also received last fall a top-dressing of manure from the pigsty and sea-weed from the shore, which was worked in with the fork this spring. The stools were thinned out severely this spring, and the ground kept in good cultivation until the fruit was set. The currant worm attacked the bushes soon after the leaves came out, and was subdued with a single application of White Hellebore mixed with water—say a large tablespoonful to eight gallons of water. Hardly a worm could be found alive the morning after the application. The mixture was applied with a garden syringe, which sends the liquid with such force that every leaf gets a drenching. Another crop of worms appeared in June, and the Hellebore made short work with them. Three things are to be observed in the application of this poison. 1. The White Hellebore should be fresh from the drug

store. 2. It should be thoroughly applied so as to wet every leaf. 3. The application should be made as soon as the worms make their appearance. The crop was remarkably clean and handsome. The cost of the production did not exceed one cent a quart."

### Tim Bunker on Too Much Going West.

MR. EDITOR: I got your letter this morning just as I had got my scythe ground and was going to mowing on that Horse Pond lot, where the grass is breast high. We use the hand-scythe occasionally just to keep our hand in. Three young men were waiting to strike in with me, calculating to give the old feller a sweat afore noon; so you see I could not possibly stop to write anything until that grass was in the swathe, and them young fellers were so tuckered out that they wished they were where the grass was lying down. That Horse Pond lot continues to be an eye-sore to Jake Frink, but it is lovely as a rose to the rest of Hookertown. Ye see, it has been giving me three ton to the acre regular every season for nigh on to twenty years, and has been preaching tile-drain and high farming to all Hookertown and the rest of mankind, through the *American Agriculturist*. It may not have been worth much to the rest of mankind, but it was a grand job for me, and has paid enough sight better than any bank stock, or Government bonds, I ever saw, twice over. It was waste land; it is a productive meadow, making money for me every day in the year. Jake never seems to have forgiven me for the change wrought, and every season, when the purple heads of the herd's-grass are blooming and waving in the breeze, he seems to be afflicted with something worse than hay fever. [The Squire still uses the early New England name of "herd's-grass" for what is called Timothy in other parts of the country, and at present the name is in frequent use in New England.—Ed.] I hope he'll get over it by and by. However, I do not lay up anything agin him; I am ready to do him a kindness any time, especially to buy another Horse Pond lot whenever he has one to sell.

There is a deal of talk now about going West, as there has been for the last fifty years, and I am about tired on't. If I read the census statistics aright, we have had enough of this business for the good of the older States, and it is about time Greeley's advice, "Go West, young man," was laid on the shelf. Up in Windham County, every farming town shows a loss of population in the last ten years, and this is true of every rural district in the State, and, probably, true of all the older States. Taking the whole State through, there has only been an increase of about 60,000 in ten years, and this is wholly in the cities and manufacturing towns. Many of the farming towns have less population than they had fifty years ago. Meanwhile, Connecticut has swallowed Greeley's philosophy whole, and is sending off millions of money every year, with her sons and daughters, to the far West. There is a clean broad belt of them all the way to the Pacific coast. Connecticut capital and muscles, invested in California soil, raises wheat and sends it back to feed her people. We import in large quantities almost everything that can be raised on the farm—beef, pork, butter, cheese, mutton, lambs, hay, vegetables, and fruit. Not a quarter of the corn consumed in Hookertown is raised here, or on Connecticut soil; it comes up to Shadtown by the sloop and schooner load—much of it already ground, and the balance ground in our mills and sold to livery stables, to farmers even, and every one who has use for corn meal. The family pig in the village, with few exceptions, is fattened on Western corn. We consume immense quantities of Western beef—fresh, corned, canned; Western pork and lard, cheese, butter, etc. While this is the case, farming property is very generally getting cheap. Farms in many parts of the State can be bought for a little more than what the buildings cost fifty years ago, or less. The buildings often times are in fair condition, enough sight better than a dug-out or the cheap frame dwellings that Eastern men are content to live in on the prairies. These old farms can be bought for from twenty to thirty dollars an acre, as the advertising agencies

show. They furnish shelter, fuel, and food for the family—the three great necessities. They are in the midst of good markets near at hand, good schools, churches, and good neighbors. The climate is about all that can be desired for Connecticut people. There may be enterprise, adventure, and romance in going away from home, but in many cases I do not believe it pays. Some men draw prizes, but a great many, blanks. I have seen too many men come back, heart sick and body sick, poor and discouraged, to take much stock in far-off homesteads.

I'm ready to give a reason for the faith that is in me. One grand reason offered for going West is lack of room here. Well, it is the easiest thing in the world to double the cultivated acres of Connecticut by going deeper into the soil. That two acres of Horse Pond did not pay the interest on ten dollars an acre; it now pays the interest on two hundred, easy; it virtually added twenty acres or more to Connecticut farm lands, and became a profitable and safe investment, as long as it is looked after. Now, we have, in almost every town in the State, large tracts of land that only need draining to make 'em yield double. Oftentimes draining will quadruple their value. But if only doubled, they would carry twice the men and twice the stock they now carry. There are large tracts of stony land, now in pasture, that can be cleared and made profitable; there are still larger tracts of sandy and light loams, called worn-out lands, that only need capital and brain manure to be made profitable. A small part of the capital that goes off with our sons and daughters, and is spread out by them all across the Continent, if concentrated upon our own acres, would quadruple its agricultural productions and enable us not only to feed our own population, but to export to other States. It is about time Connecticut attended to its own business and turned the tables on the West.

There is nothing like the "*Argumentum ad hominem*," Mr. Spooner says, and I guess he is about right. Take my John's case. He went to the war, you know, and came home with his head full of notions, and nothing would satisfy him but he must go away from home. I knew there was nothing like experience to teach people; and rather favored his going. Well, he went to Kansas ten years ago, took up land, pre-empted, and homesteaded, lived in a dug-out, built a frame house, raised wheat, corn, oats, and potatoes, for about four years, on soil from nine to ten feet deep; no end of crops, but poor market; got discouraged; went to clerking; made some money, but spent more. After ten years hard work, under more than average good circumstances, he comes home this season with a wife and two children, and two thousand dollars indebtedness above the value of his real estate. We cannot tell, of course, what is in the future, but the result of ten years' work, in the prime of life, is rather a poor commentary on the wisdom of his course. In this short life a man ought to post the books once in ten years, and look results in the face. Half the money he has spent and earned in the last ten years, if invested here in Connecticut, would have given him a good farm, a good paying business for life, without any debt. From the Hookertown outlook and observation, we think there is quite too much talk about going West, stick by the old homestead, deepen the soil, use brain manure, and prosper.

Yours to command,

TIMOTHY BUNKER, Esq.

Hookertown, July 10, 1880.

[Squire Bunker has so much sound sense that we always allow him to "say his say," even when we do not altogether agree with him. In view of his son's experience, we can hardly blame him for taking the view of things that he does. If every Connecticut farmer were as skillful, as wide awake to improvements, and so well understood "manuring with brains," as he does, the Squire's advice for the sons to stay on the old farm would have more force. But the Squire knows many farms in Hookertown that are capital places to go from. The fact is, there is much to be said on both sides; it would be better for some to stay, and better for others—far better—to go West or anywhere else.

We advise the Squire to hurry up his fall work and take a Western trip himself. He will find there grand farms, such as he never dreamed of, and splendid openings for enterprising young men from the Eastern States, and from the Western ones, too. Still he is right about the capabilities of Connecticut and of the other older States. There is many a horse-pond to be drained, and have its value increased many fold. There is many a farm that needs only "manuring with brains" to have its product doubled, to the profit of those who do it. This country is so large that there is room and work for all the Squire Bunkers who know how to stay at home in the East, and the young men who, whatever may be said, will "go West."—Ed.]

### Science Applied to Farming—LX.

#### Among Our Field Experimenters.

I have lately had the pleasure of visiting several of the gentlemen who are making the field experiments with various kinds of artificial fertilizers proposed by the *American Agriculturist*.

Mr. Charles Fairchild, of this place, is now working the fourth season. His trials on small plots, confirmed by experience in his field practice, indicate quite decidedly that he can get good crops of corn, potatoes, grass, oats, and wheat, with a mixture of fine bone-dust and muriate of potash. He buys the bone-dust at a neighboring bone-mill, very finely ground, at \$32.00 per ton. The muriate has cost this season some \$40.00 per ton. He uses, as I recall, from 150 to 250 lbs. of the potash salt, and 200 to 400 lbs. of the bone-dust per acre. Reckoning actual cost of fertilizers, labor, interest on value of land, and all other expenses, he calculates that his corn costs him 40 cts. per bushel. Some of his neighbors adopted his plan last season, and had a like experience. I confess I am a little surprised at his good success in growing wheat with fertilizers containing no more nitrogen than the very small amount found in the bone. Nor am I by any means certain that for wheat, oats, and for potatoes also, it would not be more profitable for him to use nitrogen in Peruvian guano, fish scrap, or some other form. It will be interesting to learn how long the supply of potash in the potash salt and phosphoric acid and lime in the bone will continue to bring him good crops.

Mr. Fairchild, in co-operation with some other gentlemen, has undertaken a very thorough study of these questions by a series of "Special Nitrogen Experiments" similar to those described in the *American Agriculturist* for May last. He has laid out a piece of nearly two acres in some twenty-five parallel plots for as many different fertilizing materials and combinations, leaving unmanured spaces between each two manured plots. He proposes to continue the experiment through a series of years, following the crops in a rotation which he thinks may prove profitable on his land. The labor will be considerable, but the results cannot fail to be very valuable for himself and for the public. As he tersely puts it, the application of what he has learned has made the difference between good profit and actual loss in his farming, and he is ready to do more work in the same line.

Mr. Chester Sage, of this place, has been experimenting on a plan similar to Mr. Fairchild's, as the readers of the *American Agriculturist* have noticed from the reports of his experiments, and has reached similar results. Potash, in potash salts, and phosphoric acid in bone and superphosphate, bring him better crops than his best barn manure, and at relatively very small cost. And I must say that I have been very much surprised to find how many farmers in this region have had like experience in their experiments and in their field practice. I had the opportunity some days ago to make a visit to see some interesting

#### Experiments on the Farm of the Maine Agricultural College,

under the direction of my friend and former assistant, Prof. W. H. Jordan, successor of Prof. Farrington in the Agricultural Department of that Institution. Several of the field experiments made by Professors Farrington and Jordan have been

detailed in the *American Agriculturist*. For corn, potash and phosphoric acid together have proved most profitable; but for potatoes and turnips the

Fig. 1.—FIRST ROOTS OF CORN PLANT.

addition of nitrogen has seemed requisite for the best results. I had quite a talk with Prof. Jordan about corn-growing with commercial fertilizers. He is persuaded that corn may be raised with profit in our older States by the use of fertilizers supplying phosphoric acid and potash. But in cooler regions, like Eastern Maine, he doubts whether farmers generally can afford to sacrifice grass, which generally does well, for corn, which sometimes fails to mature. He is persuaded, however, that where the climate favors corn, it may be grown with the cheap "mineral" fertilizers, as stated above, and thus enabled to gather its nitrogen from soil and air; that if corn and stalks are fed out on the farm, this must prove a very economical way to make manure, and that it is much better to have the corn get the nitrogen for itself, than to buy it at from 20 to 30 cents, or more, per pound in commercial fertilizers, as so many thousands of farmers are doing. I am sorry that lack of space forbids my mentioning in detail the experiments and experience of a number of other gentlemen whom it has been my good fortune to visit. Mr. W. D. Bartholomew, of Putnam, Conn., whose name is already familiar to the readers of the *American Agriculturist*, is continuing his field work this season. With corn, he, too, finds the only artificial fertilizers that do much good are those that supply phosphoric acid, bone and superphosphate; but with potatoes, potash salt and nitrogenous materials, guano, sulphate of ammonia, nitrate of soda, etc., are profitable; and with corn, by far the best results come with farm manure and superphosphate together. Indeed one thing I notice in the talk of all the experimenters is that along with the more rational use of artificial fertilizers, they are likewise studying, and very earnestly too, how best to increase the production and improve the quality of their farm manures.

#### Letters from Experimenters.

Mr. H. M. Swift of Chestnut Ridge, N. Y., in speaking of his repetition this season of his last year's experiments says, "A great desideratum in

Fig. 2.—YOUNG CORN PLANT WELL ROOTED.

my vicinity is a crop to follow corn. Spring wheat never did well with us, barley is very uncertain, and oats, formerly the best of all our farm crops, have for some years been a failure. The straw is long enough but always more or less rusted and the grain light." He queries how far the rust is due to climatic or other conditions beyond our control, and how far to defects in the soil which fertilizing and tillage may overcome, and is at-

tempting to get some light upon the problem by experiments. I hope he will favor us with his results. One difficulty, in fact one of the greatest difficulties with field experiments, is in the disturbing causes which affect the yield on the several plots where the comparative trials are made. Besides original variations in the depth, texture, water supply, and composition of the soil, there are, as Mr. Swift suggests "very unexpected differences within limited spaces due, in lands long cultivated, to the droppings of pastured stock, to the foddering on the ground of a stack of hay, to the deposit of a load of manure or perhaps to the use of some fertilizer which, producing no immediate results, in time, with change of culture and appropriate crops, show its effects long after the cause is forgotten." Mr. Swift adds further on in his letter, and, as it seems to me very pertinently, "I think I have generally aimed at this residuary fertility, if I may so call it, rather than the first effects."

Fig. 3.—THE ROOTS OF CORN PLANT AT A LATER STAGE.

Mr. J. W. Pierce, of West Millbury, Mass., who is also repeating his last year's experiments, writes: "The nitrogen and potash look much better than last year's, probably because I applied them broadcast. Last year I put part of them in the hill, and they injured the germination of the seed." I quote this observation of Mr. Pierce, because it touches a very important matter. A vast deal of harm is done in the use of concentrated fertilizers by putting them too near the seed. The seed, the just germinated plant, and the roots suffer, and the growth of the plant is checked in consequence. Farmers often think they must put the fertilizer close to the plant, or it will not get the benefit of them. They do not realize how widely the roots extend, and what a capacity they have for gathering up the nonripping materials that are diffused through the soil, and how much better it is to supply these materials so that the roots may thus gather them from the soil all about them in the natural way. This suggests a very important subject:

#### The Roots of Plants.

The roots of a plant give it mechanical support during its growth, and gather for it food, with water, from the soil. When this work is done and the crop is gathered, the roots remain to contribute their own substance to supply food for the succeeding crop, to hasten, through their decomposition, the processes by which the plant food of the soil is made available, and finally to improve the texture of the soil. Roots are more important agents in the growth of our crops than most people think. Every farmer and gardener ought to understand, and would work to much better advantage if he did properly understand, how roots grow and do their work, and hence how the plants should be cared for so as to best promote

the development of the roots, and in consequence the growth of the whole plant; its fruit, grain, etc.

#### The Roots of Indian Corn.

A German investigator, Dr. Thiel, has made some very interesting studies of the roots of plants, and has published several series of photographs of whole plants, tops, and roots, just as they grow in the field. From a series of these which illustrate the development of Indian corn, or Maize, as it is generally called in Europe, our engravings are taken. To get these photographs, the youngest plants, with the roots freed from earth, were put in water, as nearly as possible in the natural position, and photographed. For the others, trenches were dug in the sandy soil in which the plants were growing, and the roots laid bare. The engravings are therefore from nature, and show just how the roots are developed as the plant grows; how they extend through the soil and distribute themselves in the upper and lower layers. Figure 1 is the very

young plant; figure 2 is a little further developed. Figures 3 and 4 are older states of the plant. Figure 3 being a view from the side, showing the extension of roots in breadth and depth, and in figure 4 we see the corn plant in the same position some weeks later in its growth. I regret that Dr. Thiel has given us no view of the matured plant among his photographs. I mistrust the reason is to be found in the fact, that in the climate of North Germany, corn does not generally mature very well.

The roots of corn extend a great distance laterally and penetrate to quite a depth in the soil, though not so deeply as do many other plants, such as clover, lucern, or even beets. But at the same time, as the engravings show, the larger share of the roots are near the surface and here most of the feeding is done. The roots that reach deepest into the soil serve to bring up a supply of water when the upper strata are dried as in times of drouth. I should like to add a

#### Request to Our Experimenters.

We hear various and widely conflicting statements as to the distance and depth to which roots go into the soil. Can not some of the gentlemen

who are about to harvest the experimental crops trace the course and extent of the roots, and give us their results in figures and such description as convenient? How far do the roots of corn, potatoes, and other crops, reach; how deep do they

Fig. 4.—ROOTS OF HALF-GROWN PLANT.

penetrate, and how far down is the feeding by the roots mainly done?

W. O. ATWATER,  
Wesleyan University, Middletown, Conn.

### The Arabian Horse: "The Panther."

The careful investigations of Ali Bey result in establishing the fact that there are six distinct breeds of the Arab horse at the present day. Some of these are confined to limited portions of Arabia, and are little known to the outside world. Another breed, the "Kochlani," not mentioned by Ali Bey among the six, is often found in treatises on the horse, and is supposed to have descended from the stud of Mahomet. The tradition of the foundation of the "Kochlani" breed, which "Stonehenge" is inclined to believe, is but another name for a distinct breed in the eastern part of the desert, is as follows: The Prophet, desiring to select mares for his stud, had a number of them that had served as chargers, kept for some time without water. When mad with thirst, they were set at liberty, and at the moment when they were near the desired water, the war trumpet was sounded for a charge. Five of the mares abandoned the water, and in great excitement galloped to the spot where they expected a charge was to be made. These five high spirited animals were thus chosen as the foundation of a stud from which a famous race of Arab horses has sprung. Whatever of truth there may be in this tradition, it is in accordance with the accounts of the extreme care with which the Arab horse has been bred. It is asserted by travellers in the East, that existing pedigrees can be traced back for 500 years; and, among the choicest animals, a certificate is always made out by the local authorities, within seven days after the birth of the foal.

The characteristics of the high-bred Arab horse are well shown in "The Panther," presented in the accompanying engraving, made from an instantaneous photograph by Schreiber & Sons. "The Panther" was bred by the Turkish Sultan, at Constantinople, and presented by him to General Ulysses S. Grant, while he was on his late tour around the world. He is a dapple gray, 15½ hands high and eight years old. The full, square head, and heavy jaws, with the fine muzzle, are well shown in side view, but the remarkable width of forehead is not appreciated unless seen from the front. The eye of the Arab horse is "full and soft, sparkling with animation on the slightest excitement; the ear is small; the neck arched; the shoulders oblique, but muscular; the withers moderately high and thin; the chest rather light in girth, but the back ribs deep in proportion, and the hips, though narrow, well united to the back by a rounded mass of powerful muscles."—The large forehead and full development of brain, indicate that

the Arab horse stands high in docility and intelligence. He is possessed of a fine temperament, and when kindly treated, is extremely docile; but when the treatment is harsh he rebels, and will fight for his just rights until he wins or until death ends his troubles. We are in this country much indebted to the Arabian for the present high position held by our horses; first, for the prominent part it played in elevating the English horse, from

THE ARABIAN HORSE—"THE PANTHER."—OWNED BY GEN. U. S. GRANT.

which our stock was primarily derived, and secondly, by the infusion of its blood through direct importations. It is not exaggeration to say that the Arab horse, in its native country, is one of the family of his owner. The history of its treatment at home has not been without its good effect in teaching us the value of care in breeding, and of kind and familiar treatment of the horse from birth. Such are the intelligence and docility of the animals

### The Polar Hare.—(*Lepus glacialis*.)

Naturalists enumerate at least fourteen species of *Lepus* or true hares, as existing in America north of the tropic of Cancer. Among the handsomest, and perhaps the most interesting members of the genus is the Polar Hare (*Lepus glacialis*), a single specimen of which is represented in the accompanying engraving. It is a native of the far north,

and according to Audubon it is to the cold and inhospitable regions of the north, the rugged valleys of Labrador, and the wild mountain sides of that desolate land, or to the yet wilder or more sterile countries that extend from thence toward the west, that we must resort to find the large and beautiful Hare we have now to describe; and if we advance even to the highest latitude man has ever reached, we shall still find the Polar Hare, though the mercury fall below zero, and huge snow drifts impede our progress through the trackless waste. Both trappers and Indians in that cold, thinly inhabited and sterile region, are sometimes saved from certain starvation by means of this Hare. One of the most interesting features of the Polar Hare, though not restricted to it, is the change in

the color of its coat to correspond with the surroundings produced by the change of seasons. The color of the Polar Hare, in summer, is of a grayish brown, with black ears, bordered with white, the breast being of a bluish gray. This color is nearly that of the earth and surrounding rocks, and serves to conceal the hare from the keen eyes of its greatest destroyers, the Golden Eagle and the Snowy Owl. As the brief summer closes, the covering

of the hare becomes whiter, and soon is pure white, with the exception of the tips of its ears. The brown color of the summer garb would make the hare conspicuous on the snow, and it could be easily seen for a great distance, but as it is, the white mantle becomes a cloak of safety. In length of body, the Polar Hare varies from twenty to thirty inches, and its weight from seven to fourteen pounds. The food in summer consists largely of berries and different kinds of small tender herbage, while in winter the tops of dwarf willows and tall grasses are eaten. "It seeks the sides of the hills, where the wind prevents the snow from lodging deeply, and where even in the winter it can procure the berries of the Alpine Arbutus, the bark of

THE POLAR HARE (*Lepus glacialis*).

when they are allowed to properly develop, that it is not to be wondered at that some tribes believe that the hare, as well as its owner, has a future existence, and that both will enjoy the "happy hunting grounds" of the hereafter.

some dwarf willows, or the evergreen leaves of the Labrador Tea plant." The characteristics of the Polar Hare are much like those of its more Southern cousins—a peculiar and interesting combination of timidity and shyness. It is not

easy to get within gun shot of them, as they constantly make off in rabbit fashion, to a safe distance, where they sit until their pursuer comes almost within range, when they move on again. They are much frightened at the long shadow of the hunter which the low Arctic sun casts upon the snow, and in this respect are like deer, and the fact must be borne in mind by the hunter, if he would be successful in capturing his timid game.

All those who have eaten the flesh of the Polar Hare agree that it is fine in flavor, far surpassing that of other hares. The species can be domesticated and become handsome tame pets. Captain Ross says, of one he had: "It could not endure to be carressed, but was exceedingly fond of company, and would sit for hours listening to a conversation, which was no sooner ended than he would retire to his cabin; he was a continual source of amusement by his great sagacity and playfulness."

From Editorial "Notes by the Way."

### An Ice-House Above Ground.

**Simple—Easily Constructed—Effective—Ice for 50 Cents a Ton.**

Ice is not only a comfort and a luxury, but it is very useful on every farm—particularly where milch cows are kept—as well as in every house. A village friend of ours, who buys his ice from the dealer's wagon, asserts that his ice bill is fully met by the saving in coal and food. He argues thus: Food, especially meats, keeps fresh and good so much longer in the ice-chest that cooking is required far less frequently in hot weather, while very much less food becomes stale and wasted—a double economy. Where ice is abundantly supplied by regular dealers at low rates it is, perhaps, usually cheaper to buy the amount needed for ordinary family use. But where much is required, and especially where the ice wagon does not come around every day or two, as is the case at country residences, it is best to have one's own ice-house.

And it is but a small matter to get up one that will hold 15 to 25 tons, and keep it well through the season.—As an illustration, we describe one we recently saw on the farm of CHARLES H. WARNER, in Lima, Livingston County, N. Y. It stands on level ground, entirely above the surface. It is a new one erected in place of a similar one that has been serviceable for 15 or 20 years. As this one cost less than \$30, all told, and is filled by the farm help when there is little else to do, we may reckon the annual expense, interest included, not over \$5, or at most \$10, for 16 to 20 tons of ice—enough to

Fig. 1.—THE WALLS.

Fig. 2.—VERTICAL SECTION.

give a large supply, say 125 lbs. a day, from April 1 to December 1. — *Description*: The base (fig. 1) is a frame of 8 by 8-inch hewn or sawed timber, forming a square 12 by 12 feet. This is laid on a stone foundation, or on corner posts set in the ground, and filled underneath with stones and mortar if accessible, or earthing up will answer. A similar square frame is made for the plates, and this is supported at the four corners with 8 by 8-inch posts, eight feet long, and by 2 by 8-inch studs, say three on each of three sides, and two as door posts on the front side. The outside (fig. 3) is covered with inch boards. Rough pine boards, somewhat knotty, will answer. Mr. Warner's cost \$16 per 1,000 feet. The cracks may be covered with narrow battening. Mr. W. thinks the battens not necessary. Inch boards, laid horizontally, line the inside

up to the plates, and the 8-inch space between is filled with sawdust. The flooring is simply boards

Fig. 3.—THE ICE-HOUSE COMPLETE.

laid upon the ground or upon small cobble-stones. The roof is only one thickness of inch boards, with batten pieces over the cracks, and is supported by three horizontal strips on each side, laid across rafters. The rafters are scantling, beveled and nailed together at the top, and set into or firmly spiked to the plates. About half of the middle of the ridge is cut out, leaving an opening 4 or 5 inches wide, and over this is a cap, supported by a saddle piece at each end of it, leaving an opening on each side under it for ventilation. The cap extends far enough over to keep out the rain. The doors are a single thickness of inch boards. The outside boards can be rough, or planed and painted to correspond with the house or other buildings.—When filling the house, 5 or 6 inches of straw and sawdust are put on the floor, and the ice packed solidly on this, but a space of 6 or 8 inches is left on all sides, which is packed in with sawdust. Any spaces or cracks between the cakes of ice are also filled with sawdust. Short pieces of horizontal loose boards support the sawdust inside the door. These are put in as the filling proceeds, and taken out as the ice is removed from time to time. The ice is filled in some distance above the plates, and finally covered over with a foot or so of sawdust. This suffices to keep out the sun and air heat. Experience proves that this surrounding of sawdust on all sides will keep the ice well during the entire summer season.—Those not having access to lakes or ponds, can easily make an artificial pond in a prairie slough, or other depression of ground, large enough to furnish ice for filling a small house like the above. In this, there is a mass of ice say 9 feet square, or about two and one-third tons for each foot in height.

### Harvesting Broom-Corn.

The quality and therefore the value of the brush of the Broom-corn depends in great measure upon the time at which it is harvested. The most successful growers agree that the cutting should begin "as soon as the blossoms begin to fall," or in other words at that time when the seeds begin to form. At this time the brush is of the best color, heaviest, and the most durable. The manner of harvesting differs somewhat with the variety and whether a particular color is sought or not. Some time before the brush is cut, the broom-corn stalks are lopped, which consists in going through the rows and breaking down the tops a foot or so below the base of the brush. The object of this operation is,

A BALE OF BROOM-CORN.

first, to keep the brush straight, and secondly to accelerate its ripening. The top of the plant still retains sufficient communication with the stalk to allow of a thorough maturing of the brush.

The tabling consists in breaking down the stalks at about 30 inches from the ground. Each two

rows are tabled together, the stalks of one row being crossed diagonally upon those of the other, thus making a sort of a "table" with intermediate spaces affording room for the cutters. The cutting is done with a sharp knife, the stalk being severed six or eight inches below the base of the brush, and therefore some distance above the point where the stalk was lopped. The brush should be cured under cover, as exposure to the hot sun renders it brittle and the elasticity characteristic of a good broom is lost. A shed of any sort will do for small quantities; for larger, a drying house will be necessary. The next step is the removal of the seed, which is done by a long toothed curry-comb, a hatchel, or if there are larger quantities, a cylinder scraper is to be employed, run by horse or other power. The brush is then put on racks to dry, where it remains until thoroughly cured and is ready for haling. Much depends upon the character of the baling; in fact, all the difference between a good profit and no profit. Compact, square bales, with even ends, and the brush so put in that it will come out straight, must be made, or only a low price will be obtained. The proper size of a bale is 3 feet 10 inches long, 2 feet wide and 30 inches deep. It should be made as shown in the accompanying engraving, stout laths being placed at the corners and the whole is securely bound by a number of wires which pass around the bale.

### The Sheep Bot-Fly.

There are a number of species of bot-flies, members of the same family (*Estridae*), and are interesting from the peculiar localities which they select to pass their larvæ state, and the trouble which they thereby cause the animals within which they reside. The ox bot-fly plants its eggs in the skin of cattle, where the larvæ grow to large size. The horse bot-fly selects the stomach of the horse for the place of its development, while other species inhabit the internal organs of mice, squirrels, rabbits, etc. The Sheep Bot-fly, or Gad-fly (*Estrus ovis*), selects the nostrils of its host as the most fitting place for the abode of its young. Figure 1 represents the female fly, which is brown, and yellow-banded. As soon as the eggs hatch, the larvæ make their way up the nostrils to the frontal sinuses, where they attach themselves by little hooks that are abundant around its mouth, and continue to feed upon the mucus always found in the location selected. This entrance takes place in early summer, and the larvæ, which are of a creamy-white color while young, gradually attain their full size and a dirty brown color. In this state the grub remains until the following spring, when it loosens its hold, and passes down the nostrils, causing great irritation and discomfort to the sheep. Figures 2 and 3 show the larvæ with the upper and lower sides, respectively, in view. After dropping from the animal, the larvæ burrow into the ground, and pass into the inactive pupa state. They remain as chrysalids for six or eight weeks, and then come forth as two-winged flies, in appearance much like the common house-fly, but somewhat larger. The flies soon provide for a new generation by depositing eggs in the nostrils of the sheep. As to the injurious effects of the Bot-fly, it may be said that opinions differ greatly. It is probable that many cases of death assigned to the bots, have resulted from other causes. However small the danger may be, the annoyance to the sheep is enough to lead flock-owners to prefer that their flocks may be exempt from attacks. The remedies fall naturally under these heads: Change of situation, prevention of the deposit of eggs, and removing the larvæ. Dr. Thomas, in his 9th report as the State Entomologist of Illinois, in his article on this sub-

Fig. 1.—FEMALE FLY.

Fig. 2.—UPPER SIDE.

Fig. 3.—LOWER SIDE.

ject is not the place for a full discussion of the various remedies proposed. The most common is the use of oil, which is supposed to destroy the larvæ. Another is the use of kerosene, which is supposed to destroy the eggs. A third is the use of arsenic, which is supposed to destroy the larvæ. A fourth is the use of quinine, which is supposed to destroy the larvæ. A fifth is the use of strychnine, which is supposed to destroy the larvæ. A sixth is the use of digitalis, which is supposed to destroy the larvæ. A seventh is the use of belladonna, which is supposed to destroy the larvæ. An eighth is the use of opium, which is supposed to destroy the larvæ. A ninth is the use of castor oil, which is supposed to destroy the larvæ. A tenth is the use of turpentine, which is supposed to destroy the larvæ. A eleventh is the use of linseed oil, which is supposed to destroy the larvæ. A twelfth is the use of olive oil, which is supposed to destroy the larvæ. A thirteenth is the use of almond oil, which is supposed to destroy the larvæ. A fourteenth is the use of peach oil, which is supposed to destroy the larvæ. A fifteenth is the use of apple oil, which is supposed to destroy the larvæ. A sixteenth is the use of cherry oil, which is supposed to destroy the larvæ. A seventeenth is the use of plum oil, which is supposed to destroy the larvæ. An eighteenth is the use of pear oil, which is supposed to destroy the larvæ. A nineteenth is the use of quince oil, which is supposed to destroy the larvæ. A twentieth is the use of hawthorn oil, which is supposed to destroy the larvæ. A twenty-first is the use of rose oil, which is supposed to destroy the larvæ. A twenty-second is the use of lavender oil, which is supposed to destroy the larvæ. A twenty-third is the use of eucalyptus oil, which is supposed to destroy the larvæ. A twenty-fourth is the use of peppermint oil, which is supposed to destroy the larvæ. A twenty-fifth is the use of spearmint oil, which is supposed to destroy the larvæ. A twenty-sixth is the use of catnip oil, which is supposed to destroy the larvæ. A twenty-seventh is the use of lemon balm oil, which is supposed to destroy the larvæ. A twenty-eighth is the use of mint oil, which is supposed to destroy the larvæ. A twenty-ninth is the use of basil oil, which is supposed to destroy the larvæ. A thirtieth is the use of oregano oil, which is supposed to destroy the larvæ. A thirty-first is the use of thyme oil, which is supposed to destroy the larvæ. A thirty-second is the use of sage oil, which is supposed to destroy the larvæ. A thirty-third is the use of rosemary oil, which is supposed to destroy the larvæ. A thirty-fourth is the use of hyssop oil, which is supposed to destroy the larvæ. A thirty-fifth is the use of fennel oil, which is supposed to destroy the larvæ. A thirty-sixth is the use of dill oil, which is supposed to destroy the larvæ. A thirty-seventh is the use of caraway oil, which is supposed to destroy the larvæ. A thirty-eighth is the use of anise oil, which is supposed to destroy the larvæ. A thirty-ninth is the use of fennel seed oil, which is supposed to destroy the larvæ. A fortieth is the use of dill seed oil, which is supposed to destroy the larvæ. A forty-first is the use of caraway seed oil, which is supposed to destroy the larvæ. A forty-second is the use of anise seed oil, which is supposed to destroy the larvæ. A forty-third is the use of fennel seed oil, which is supposed to destroy the larvæ. A forty-fourth is the use of dill seed oil, which is supposed to destroy the larvæ. A forty-fifth is the use of caraway seed oil, which is supposed to destroy the larvæ. A forty-sixth is the use of anise seed oil, which is supposed to destroy the larvæ. A forty-seventh is the use of fennel seed oil, which is supposed to destroy the larvæ. A forty-eighth is the use of dill seed oil, which is supposed to destroy the larvæ. A forty-ninth is the use of caraway seed oil, which is supposed to destroy the larvæ. A fiftieth is the use of anise seed oil, which is supposed to destroy the larvæ.

ject, says: "I am satisfied that high, dry, firm, open, airy situations will be found much less infested with this pest than low, moist situations, where there is thick undergrowth, and close, hot air." The most common method to prevent the deposit of eggs is the tarring of the nose, which should be done at frequent intervals during the fly season. After the grubs or larvæ are once seated in the nostrils, it is a difficult matter to remove them. The use of some irritating substance that will produce violent sneezing is, perhaps, the only method to be pursued.

### Among the Farmers.—No. 56.

BY ONE OF THEM.

Since I wrote last, I have been at a plow trial. The managers of the trial were conscientiously earnest about having a trial of plows which would develop their best points for general utility. I am rather old-fogyish, and stick to an old-fashioned 19½ plow (with a reversible point, however,) as the best plow I know of for my light team and gravelly, stony soil; but this did not hinder the Secretary from asking me to come out and try the dynamometer on the plows. I did that, and a good deal more, for I watched that whole trial, and criticised it well—in my own mind. Not being a member of the committee, but only an adjunct, I discussed nothing except the draft with them, and do not know which plow won the prize. The trial was in this wise: Each plow had its plowman, who drove his own team, and who was coached by his principal and all his friends. The teams were all started at about the same time, making a sort of a plowing match of it. Each plowman plowed a quarter of an acre of beautiful flat, mellow land. The first half was laid with flat furrows; on the rest, the furrows lapped. At the close, the plows and teams all came to a plot selected for the purpose, where the draft of the plows was tested. I was surprised at several results. We tested all the plows first with a "jointer," or "skim"—that is, with a small plow attached like a coulter to the beam. The jointer cuts less than half the width of the plow, running only about two inches deep, and folds half the sod over upon the other half, and then the whole is rolled over into the furrow by the plow. After this, the plows were tested with coulters. I was surprised to find that all the plows showed less draft with the jointers than with the coulters. It was shown also that, in this soil—and it is probably true of other soils, except those full of very tough roots—a mere scratch of the coulter cutting possibly an inch and often less, answered every purpose, enabling the plow to turn a true, straight-edged furrow, and with notably less draft than if the coulter were set as low as is customary. I have always felt as if the coulter ought to be in the ground "deep enough to do some good," never having the idea that an inch-cut was just as good, and better, than a three or four-inch one, besides making a saving of at least 50 lbs. in the draft, but such seems to be the case.

Fig. 1.—COULTER HIGH.

It is clear that it takes much less power to draw a coulter if it cuts but one inch, than one cutting four inches. Now, the coulter is, or should be, sharper than the edge of the mould-board in front

Fig. 2.—COULTER LOW.

of the standard, and, it would seem, should cut the sod and grass-roots much easier, but it appears that the advantages of the deep-cut are more than offset by the power required to force the coulter through the ground to that depth. Let us suppose that figs. 1 and 2 represent coulters attached to plow-beams. Fig. 1 is supposed to cut an inch, and is set where the furrow-slice just begins to be lifted by the share, driven as a wedge under it, which is the proper place, and varies with the depth. Figure 2 shows a coulter set forward, and considerably deeper, while Fig. 2 shows one nearly perpendicular. The lightest draft occurred with a coulter set as shown at fig. 1. Doubtless the roots part easier for being slightly strained, and the very small depth of the cut is sufficient. Fig. 2 is a faulty position, both as to depth and angle. We were discussing the question why it was that the jointer showed less draft than the coulter, and came to these conclusions: In the first place, the cut of the jointer is very shallow, hence consumes little power; then the weight of the slice when turned is laid over upon the outer edge of the main furrow-slice, as shown in figure 3, relieving the plow of its weight where it would have to lift it, and placing it where

Fig. 3.—DIAGRAM SHOWING ACTION OF JOINTER.

it helps by its own weight in the turning. The figures indicate the lift of the furrow-slice and the corresponding position of the outer edge.

In most soils it requires half as much again power to draw a plow seven inches deep as to draw it six. This we saw illustrated in the difficulty the committee had to make the plowmen hold to a seven-inch furrow, and the difference it made in the indications of the dynamometer whether or not that depth was kept. When two inches are taken off the top, of course, that is to a degree equivalent to plowing only five inches deep. The plow *detaches, lifts, twists, turns*, and in these operations *crumbles* the furrow-slice, and the thinner it is, the more easily will each one of these operations be done.

#### As to the Testing of Plows.

As it was, it was interesting, but so is a horse-trot, no matter how much jockeying is going on. It was very funny to see how well the plowman and his principal understood each other

"Put her down there—put her down, beam deep if they want it so," said the principal; "there, that's seven inches—that's eight, easy enough. How does that read on your 'dynamometer'?"—"Only six and a half deep, anyway," said the committee-man, "and there's no use in taking down the indications of the dynamometer."

"Let her go down, then; raise the wheel; let out your trace-chains: get her down some way," repeats the principal, just as honestly as if he meant it; but the shrewd plowman only pretends to do what he is told, and bears down hard enough on the handles to more than balance the difference. So it went, more or less, but enough to vitiate the results, and so it will always be, if the plowman is personally interested in securing unfair results. I understand that the committee suggest that, if another trial be held, the work shall be done before the committee inspect it, under the direction of the superintendent, or of some suitable person, of course. This may be very wise, for it is very difficult to separate the plowman and his manner of plowing, his team, and the appearance of the plow itself from the actual work done, which alone is the real criterion, when compared with the power required. As to a dynamometer test—that is, to get accurately at the power required—each plow

should be driven at different depths, accurately gauged at different widths of furrows, with different attachments—that is, with coulters, coulter-shares, jointers, and revolving coulters; and all the plows should be held by one man, and drawn by the

Fig. 4.—SECTION OF SMOKE-HOUSE.

same team, and that a much more powerful one than is necessary, and one to which the plowman is accustomed. I think that excellent, satisfactory, and very useful results might be thus attained.

#### Smoke-house, Ash-pit, and Boiler-house.

Some Litchfield County farmer folks are planning a building to serve as a smoke-house, ash-pit, and boiler-house, and consulted me. I send you a sketch of the plan proposed. They have a grove of maples, the remains of an ancient sugar-bush, and this furnishes them all the sugar they need throughout the year. I therefore introduced a Cook's Evaporator, which is for boiling far superior to a kettle or cauldron; though the kettle is necessary for heating water, and for boiling pig-feed.

The walls of the building will be of stone, not less than 14 inches thick, laid in cement mortar; the inner walls a foot thick. The ash-pit is planned to occupy nearly the whole of the 6 by 6 smoke-house; room being left at the door to enter and set the fire, which is placed under a stone slab laid in the wall, as in fig. 5, 14 to 16 inches above the ground, with an opening at the back in the rounded corner. This inner wall is three feet high, with good top stones, so that it may be used to stand upon to hang the bacon. Figure 4 shows how the roof should be framed, so that the smoke-house may be eiled with tongued and grooved boards, ventilation being provided at the chimney, and in the door besides, if necessary. The door should be close-fitted and strong. The ash-pit should have an opening for taking out the ashes, made to fit a good-sized flagging-stone, by which it is to be closed on the outside. This hole should be made perfectly tight by plastering around the stone door with clay and wet ashes. The kettle is set in brick, the fire-place opening towards the side door. The plan includes a Cook's Evaporator for sap or sorghum juice. When this is used, the fire is made under the end of the evaporator pan, *E*, set in brick, the flue passing under the kettle, *K*. This flue must be closed by an iron slide when not in use, and the door of the kettle furnace must be closed

Fig. 5.—PLAN OF BOILER AND SMOKE-HOUSE.

up and plastered up with clay, if necessary, when the evaporator is used. The sap, first put into the well-cleaned kettle, would have the chill taken off from it at least, and perhaps get quite hot before

it is placed in the evaporator, where the process of evaporation and skimming would take place.

#### Picking Fruit.

I was in one of the principal seed stores in New York a few days ago, when a buyer came in to inquire about fruit pickers and baskets. He wanted,

Fig. 6.—PICKING WITH A BAG.

particularly, baskets to take into the trees to pick apples. I asked if he did not pick into bags, and found neither he nor the seedsman had ever heard of such a thing. I think it would be quite worth while for you to illustrate the method of picking by a cut similar to the one in Thomas's "Fruit Culturist."—[We reproduce in figure 6 the cut referred to by the writer—Eds.]—We tie a small apple into one corner of a grain bag, selecting a rather large-mouthed bag; then tie this corner to one edge of its mouth, by means of the bag string, taking in so much of the bag that the cord will not cut the shoulder when one's head is put through, and the bag hung from one shoulder, mouth in front. With this, the picker has both hands free, and can climb about in the tree as much as he pleases. When he has picked half a bushel or so, he will begin to find the load burdensome. He empties the bag into the barrel without bruising the fruit by lowering the bag into the barrel, and then gently drawing up on one side, letting the apples roll out, as shown in figure 7.

#### How Rid the Ground of Wild Mustard.

—The Wild Mustard, *Charlock*, *Brassica* (formerly *Sinapis arvensis*), is one of the weeds imported from Europe, and is troublesome in the grain fields of some parts of this country. The seeds retain their vitality for so long a time, and are produced in such abundance, that when once in the ground it is a hard matter to eradicate this pest. As the Mustard plant is an annual, and must come from the seed each year, it is evident that if the plants are not allowed to go to seed, the eradication must

Fig. 7.—EMPTYING THE BAG.

be effected in time. The cereals are the crops that offer the best opportunity for the development of the Mustard, and when the ground is badly infested, to pull out the plants is a great deal of work. In such case, it would be best to grow some crop that will allow the ground to be frequently cultivated. Instead of sowing barley, plant the ground to corn, even if

when a crop of roots, beans, or potatoes should be put in. The beans and early potatoes will be off in time for winter wheat, and the ground is then seeded down to grass. With this method of thorough culture for two or three years, the weed can be thoroughly removed from the ground. Seed-grain brought from some other locality, should be examined for Mustard or any other foul seed.

#### Dome-shaped, Concrete Spring-house.

We were so much struck with the practical character of a novel plan for a spring milk-house, which a friend proposes to erect, that we requested him to furnish the sketches of the same here given.

Figure 1 is a view of the building. The inside diameter is 10 feet. It is 8 feet high. The walls

Fig. 1.—FRONT VIEW OF SPRING HOUSE.

are 18 inches thick at the base, and a foot at the top, and to be made of concrete; that is, cement-mortar—one-third cement, two-thirds sand—in which as many stone chips from a quarry are placed as can be completely bedded in, *submerged*, so to speak, in the mortar. This should be handled when fresh-mixed, and as liquid as possible, and and yet set solid. There will be a complete dome, built of hemlock boards; the concrete will be laid upon that, and it is proposed to have it quite rough on the outside, so that vines will cling to and cover it. The door will be a very strong and tight one, horizontally and diagonally boarded, of matched pine, fastened throughout with clinch-nails. Ventilating doors, opening outwards, are shown in the front, and this opening will be protected on the inside with wire cloth. The building is lighted by a circular plate of rough glass, such as is used in floors under sky-lights, fully half an inch thick, and two feet in diameter. Possibly a less diameter will answer for this purpose.

Figure 2 is the ground plan. In this, *B* is the door, entering at which we come upon the cement

Fig. 2.—THE GROUND PLAN OF SPRING HOUSE.

floor, *F*, which is half surrounded by the pool against the wall opposite the door, which opens towards the north. The pool is designated by *W* in the plan, figure 2. The spring is supposed to rise through its pebbly bed at *S*, and there is a partition at *A*, over which the water flows, and which consequently separates the pool into fresh water, and that less directly from the fountain head, with probably a difference of one degree in the temperature. The temperature of the spring is about 50° in winter, rising several degrees in the hottest weather, in its present unprotected condition. It is hoped that when the spring-house is built, a temperature of 52°, at the highest, will be secured.

The pool will have a raised rim six inches wide, and three or four inches high, to prevent water splashing out upon the floor, at about the level of which the water is intended to stand. In this pool the milk will be placed in "coolers" in the coldest part. Jars and stone pots of butter may be placed in the pool nearer the outlet. The temperature of the room will probably not fall below 45° in winter, nor rise above 60° in summer. During the summer, therefore, the cream will ripen for churning in the spring house, but in cold weather it will have to be brought to the house before churning.

Figure 3 is a section on the line *A...B*, which is through the doorway. This shows the depth of the pool; the foundations, also laid in cement, so as to exclude surface water entirely; the window in the top, the form of the entrance, etc. The outflow of water takes place at the part of the pool farthest from the spring. At this place, outside of the building, a cement trough is planned, so that animals may drink, and where the rinsing and washing of some of the utensils may be done. A channel will surround the floor, for conducting away any water that may be spilled upon it. The ventilation in the door, coming, as it does, very near to the highest part of the dome, which is 7 feet high inside, is supposed to be abundant. The light may be too great on sunny days, in which case a screen on the outside will keep out both light and heat. Light is, however, no disadvantage in a dairy if unaccompanied by heat and flies. As to warmth—in case it should seem best to use such a spring-house in winter to work the butter in, it would be necessary to heat it. This could easily be done by using a

Fig. 3.—SECTIONAL VIEW OF SPRING HOUSE.

charcoal stove from which no odor would come. The pipe should lead directly up and out through a 24-inch hole. A 2-inch pipe would undoubtedly draw well, and take off all the gases of combustion, which, from their being odorless, are dangerous if not carried away. Sufficient warmth to make the room comfortable would not affect the temperature of the pool perceptibly, unless very long continued. Should the size strike any one as needlessly large and expensive, it may be reduced, say, eight feet inside diameter and six feet high, or six in diameter, and of proportionate height—the pool being in this case a good deal contracted in size, and the floor lowered to secure head-room.

**Milking Three Times a Day.**—This matter has been discussed in our columns in former years, though but little has been said on the subject of late. The following, from one of the Cow Essays which will appear in the book, comprising the Prize Essays and others, gives the views of "Spencer" on the propriety of milking three times a day:—"During the heat of summer, the cow should be milked three times a day, at regular intervals—about five o'clock in the morning, one in the afternoon, and nine in the evening. The quantity of milk and butter is considerably increased, and the quality improved, by this practice. The milk is injured by remaining in the udder through the heat of the day, and the cow is made uncomfortable, which, of necessity, diminishes her usefulness. When cows are milked but twice a day in hot weather, the udder becomes too much heated and feverish, and the milk is in a similar condition—the cream seems to be melted, the milk soon becomes sour, the cream does not rise well, and the butter is soft and oily. These difficulties, almost

universally attending butter-making at this time of the year, are mostly overcome by the practice of milking three times a day, and the cow being near at hand it is a small matter to adopt this practice."

### A Mud and Muck Digger.

Mr. H. H. Hooper, Bedeque, Prince Edwards Island, sends sketches of an apparatus for digging that is now used quite extensively by himself and others in getting out the mussel mud largely employed in that region as a fertilizer. As it is not patented, and may be advantageously used

Fig. 1.—A MUD AND MUCK DIGGER

in many cases in getting out muck, we give it for the benefit of those who have use for such an affair, whether to restore to the land some portion of the fertilizing material that is always running into the sea, or would make use of the fertilizing elements contained in the slowly decaying vegetable matter of bogs and swamp holes. The lower portion of the long handle (fig. 1) has strong iron

Fig. 2.—THE SCOOP.

bolts placed every six inches apart, which come against an iron dog in the frame at B, and serve to hold the scoop in place while being filled. If the mud or muck is hard, the end of the frame may rise up, it being provided with a hinge at A. The scoop is worked by a horse attached to a capstan. The whole machine as arranged for work is shown in figure 1. The scoop is made as shown in a larger view in figure 2; and is provided with a sliding bolt, A, which, when pulled out, allows the scoop to fall and empty itself. A portion of the upper part of the capstan to which the horse is attached is shown in figure 3. The wheel, A, which carries the chain, cable, or rope, as the case may be, is set loose by means of a small lever, with a cord attached, B, which comes against broad bolts and holds it when the scoop is being raised.

3.—PART OF WHEEL.

### The Collecting and Uses of Rock-Weed.

The Rock-Weed, or Blister-Weed, as it is sometimes called, (*Fucus vesiculosus*), is one of the most valuable of marine plants, and in general use, as a fertilizer, in all the shore towns, where a rocky coast favors its growth. It takes its popular name from its habit of growth upon rocks that line the shore. It clings fast to the boulders wherever there is room, and the foliage (as its fronds may be regarded), hanging in loose tresses, about eighteen inches long, completely covers the rocks. The

plant is left more or less bare at half tide, on the ebb, and from that time to half tide on the flood, can be readily gathered by the hands. It is thrown into large baskets and piled on the shore, or carried directly to the cart and drawn to the fields where it is to be used. Farmers more remote from the shore, and persons who make a business of selling sea wrack, transport it mostly in boats and large scows, which are pushed in among the rocks, and loaded, so as to be got off at high tide. The law of the sea makes all wrack, below high water mark, common property that may be removed at any time by water; it cannot be carted off over

the land, without the consent of the owner. This gathering directly from the rocks during the summer, furnishes an article of the highest value as a fertilizer. Later in the season, during fall and winter, it is torn from the rocks by the storms and driven ashore, mixed with eel grass and other marine

plants. This is much more easily gathered but is not near as valuable. The clear Rock-Weed, where farmers are acquainted with it, has a standard value and sells as readily as stable manure. Many laborers who do not have steady employment improve their leisure in gathering it, and the piles upon the wharves and shore never fail of purchasers, at remunerative rates. It is put to quite a variety of uses and is most prized by those who are best acquainted with it. It is not a concentrated manure, but is thought to be more valuable than the common yard manure. It is excellent for top-dressing pastures or meadows, and the effects are seen for several years, in the larger growth of grass, and in the improvement of its quality. It is a favorite fertilizer for ruta-bagas and the rock turnip. Trenches are opened, filled with the weed, and covered with four or five inches of soil. This never fails to bring a good crop—with fair cultivation. It is also highly prized for cabbages and potatoes, spread broadcast and plowed in, or put in the hill. One of the best pieces of corn in town is upon a sod manured with Rock-Weed, spread broadcast and turned under last spring. It is an admirable thing in a compost heap made of muck, headlands, and any other refuse material, and throws the whole mass into fermentation as readily as stable manure. We have used it a good deal in the sty, and there it operates as an absorbent and subdues immediately all unpleasant odors. Valuable as this weed is, but a small portion of it is gathered. It sells readily as it is discharged upon the wharves, at from one to two dollars a ton, and at these prices is a very cheap fertilizer for all farmers along the coast. CONNECTICUT.

### A Plan for a Small Barn.

There are many small farmers, villagers, gardeners, etc., who wish only barn room enough for a single horse and carriage and a cow. To such, the requirements are cheapness and durability, combined with convenience; and with these points in view we give the following plan of a small barn, designed by Prof. G. T. Fairchild, of the Michigan Agricultural College. Three barns have been built on the College grounds, after this plan, and are used by the professors, who speak in high terms of their adaptability to the wants of those wishing a small horse and carriage barn. A view of the barn from the front is shown in figure 1, and while plain in its construction, is pleasing in outline. The first floor (fig. 2) is 20 by 23 feet, and 8 feet between joints. A large sliding door, a, 9 feet wide, admits the carriage with the horse attached, which, when unhitched, is led through the sliding door, b, into the stable. The small stable door, c, opens by hinges inwards, while the back door, opening to the manure yard, moves upon rollers. Two small windows, e, e, give sufficient light to the stable. The hay-rack and feed-box for the stalls are shown at f, f, f, each having a hay-shoot leading from the

floor above. The grain-bins are neatly arranged under the stairway, these being three in number, ranging in contents from 50 to 10 bushels. The second story, or hay loft (fig. 3), is 6 feet from floor to plates, and gives ample room for the storage of hay and straw. The stairway is in one corner, a, and out of the way; b, the door for the entrance of the hay and straw; c, c, c, ends of the hay-shoots;

Fig. 1.—A CHEAP SMALL BARN.

d, ventilator; e, e, windows. The ventilator serves the purpose of a shoot for throwing down the straw used for bedding, and has a number of openings for this purpose at various heights, including one at the bottom for cleaning out the dust, chaff, etc., that is constantly accumulating from the loft.

The cost of the barn thus described will vary according to the locality and the price of lumber, etc. The estimates for the Michigan barns were \$300, above the foundation, with two coats of paint;

Fig. 2.—GROUND PLAN OF BARN.

but in most states the lumber would cost more than in Michigan, and the estimate for this small barn would be correspondingly increased.

**Sheep for Fertilization.**—Where sheep are kept for the double purpose of direct income in wool, mutton, etc., and the manure they make, it is important that the extra food, or that outside of what the pasture furnishes, should be chosen with care. It would be wise for the American farmer to become better acquainted with cotton-seed cake, linseed oil-cake, and like concentrated foods. By feeding, and feeding liberally, of such foods, the sheep not only grow rapidly, but the manure they make is rich in nitrogenous matters and valuable fertilizing salts. The growth of animals is a means

Fig. 3.—THE LOFT.

to an end, and when the most money is made from the flock, and the land enriched, the most rapidly the end is gained. The profit of sheep as fertilizers depends largely upon the kind of food that is used.

### Silt-Basins—A Secondary Use.

A Silt-Basin is a small cistern made in the course of a drain for the purpose of arresting the flow of the water, in order that the fine particles of sand, etc., may be deposited in the bottom of the basin, and thus prevent the clogging of the drain. This is the primary use of Silt-Basins, and for this purpose they are, or should be, placed at those points where a given fall changes to a less rapid one, and the flow is not sufficiently great to carry the fine

particles of soil (silt) on to the end of the drain. The materials used for, and the modes of construction of, Silt-Basins are various. In cases where a number of drains enter the main at the same place, the Silt-Basin should be at that point, and may be made of brick, as shown in fig. 1. It will be seen that the inflowing pipes are placed some distance above the outflowing one, thus arresting the flow of the water in a pool of some depth, during which stoppage the silt is deposited at the bottom of the basin, as

Fig. 1.—LARGE SILT-BASIN.

shown by the dark mass below the water in fig. 1. A large flat stone or heavy plank is used to cover the basin; by removing this, the working of the drains may be examined, and the silt removed. A small Silt-Basin for a single drain may be constructed of a drain tile six inches or more in diameter, according to the capacity of the drain. Such a Silt-Basin is shown in fig. 2, the top running to the surface, and is covered with a flat stone, etc. A second use of the Silt-Basin is that of ventilation, as recently brought to notice by Mr. J. J. Mechi, who says:—"When drains are recently made, we seldom have complaints of their not acting, and this because air has free access to follow the water; for drains are like taps in a cask, they cannot discharge unless air is admitted at the vent-hole, for the water will not flow; so it is in stiff or dense soils which, when consolidated by time and pressure, pass both air and water very slowly." Mr. Mechi gives an instance, where he changed the outlets of some of his drains, and the ventilation of them was much diminished by the operation. "The drains became gradually less active, and we ascertained that it arose from the air not passing into the mouths of the drains so freely as it used to do." For purposes of thorough ventilation of the drains, nothing could answer so well as properly constructed Silt-Basins, where the mouth of the inflowing pipe is placed above the outflowing one, thus giving a free access of air to the throat of the drain. With this double use of the Silt-Basins—namely, the keeping of the drain free from silt, and providing an abundance of air for the free flow of the water—they should be important features in a perfect system of farm drainage.

**A Clod Crusher.**—A very cheap clod crusher can be made by fastening a number of poles to-

gether as follows: The poles are all cut of the same length, and placed side by side—about a dozen of them. A chain is fastened the whole length of each end of the series of logs by means

A LOG CLOD CRUSHER.

of staples, which are driven through the links and into the ends of the poles. The two side chains are then brought together beyond the poles and fastened to the whiffle-tree of the horse, or the double-tree of the team, that is to draw the crusher. Being flexible, the crusher conforms to the unevenness of the surface. This quickly-made implement may be used for smoothing the surface, or for spreading fine manure evenly over the ground.

### A Spring Gate-Latch.

"W. A." Springfield, Mo., sends sketches of a handy, home-made gate-latch. Mr. A. had a lot of old springs from a worn out lounge, and, wishing to put them to some good use, hit upon the following device for a gate fastening. A sliding bar of hard-wood was made, as shown in figure 1, one end being shaved round, and of two sizes. A wire

Fig. 1.—THE PARTS SEPARATE.

spring was then coiled closely around this cylinder portion, the ends of the wires being bent to fit within the coil. The latch-piece and the piece with a small round hole, to receive the opposite end of the sliding bar (two forms), are shown separate in figure 1. The whole latch complete, and in position on a gate, is shown in figure 2.

There are no definite measurements for a latch of this kind. The one described is made of 2½ inch stuff, 1½ inch thick. Mr. A. says: "I have had some of these latches in use for over two years, and would not exchange them for any contrivance I ever saw for the purpose. I have them on all the gates on the place, and on one stable door. They are easy to open on horseback, and when the gate comes to, it is fastened when shut. Nearly every

Fig. 2.—THE LATCH COMPLETE.

day, some one stops to examine the one on the front gate, to see how nicely the spring-latch works."

### A Wheat Cultivator.

"W. A.," Springfield, Mo., gives an account of his success in cultivating wheat, and sends a sketch of the cultivator which he made for the purpose. The accompanying engraving very clearly shows the construction of the implement. The head-piece through which the teeth (ordinary harrow

teeth) pass, is of hard-wood, 2 by 4-inch stuff, and 5 feet in length. The shafts are fastened to the top of the head-piece by carriage bolts and extend forward with two cross-pieces, one to unite the ends and furnish an attachment for the clevis, and the other midway to give the necessary strength. A roller, made cheaply of boards, is placed just in front of the middle cross-piece, and is 18 inches in diameter. The handles are fastened to the sides of the shafts, and run upward and backward, as shown in the engraving. The practice of cultivating wheat is growing rapidly in favor, the chief obstacle to its general adoption being the lack in the market of a proper cultivator. This needed implement will come as the demand increases.

The cultivation of the wheat should begin so soon as the rows are visible, and the operation repeated at least twice before the ground is frozen. One cultivation in the spring will usually be sufficient. The advantages of wheat cultivation are: the saving of at least one-half of the seed, as the rows must be

A HOME-MADE WHEAT CULTIVATOR.

further apart; keeping the ground clear of weeds; a greater yield; and last, but not the least, as experience teaches, less liability to the attacks of the Hessian fly, and therefore a surer crop. Further, each plant has space to tiller and spread over the ground, so that there is much less danger from smothering by deep snows than when thickly sown.

### A Hand Cart for the Farm.

There are many occasions on the farm when a wheelbarrow will not answer the purpose, and a hand cart is just the thing to save hitching up the team. A large cart with good sized wheels is a

A HANDY HAND CART.

handy implement. The one we have used for a long time was made from the hind wheels of an old road wagon. A new axle was made and the irons fitted as carefully to it as if it were a wagon. The tires were re-set and the "running gear" was therefore about as good as new. A "body" was made out of sound two-inch oak stuff, thoroughly bolted together, and upon it the bottom boards were nailed as shown in the engraving.

It was found convenient for many things to have a box, and one was made of pine boards, which fastened (by means of projecting corner and side cleats) into six holes bored in the frame. A rest-stake—an old broom handle cut down—was attached to the front bar by means of a leather loop, so that it could be thrown over on to the bottom of the cart when not needed to hold the handle from the ground, as shown in the engraving.

We do not know how much, or rather how little, this handy hand cart cost, but it is certain that it would be missed from the farm if it should be taken away for a single week. It is just the thing for carting small quantities of green fodder, grain, etc., for a short distance. As it is a gentle grade

from the barn down the lane, the cart is frequently used for taking tools, seed grain, etc., to the fields as they are wanted, thus saving the team from leaving their work and a loss of time.

### An Ice-House with a Cool Room.

The requests to give a plan for an Ice House which shall contain a cool room, are numerous. Some ask for a room in the house which may be

Fig. 1.—ANOTHER WAGON JACK.

used as a dairy, while others wish an apartment in which meat and other provisions, fruit, etc., may be stored. A plan of an Ice-House with such a room was given in January, 1879, which is as simple as anything of the kind. Those who have had the most experience in such matters do not approve of

Fig. 2.

the plan of combining an Ice House and Refrigerator in one. Aside from the fact that it is often desirable to place the ice house at too great a distance from the dwelling for the convenient use of a refrigerator, the two things—Ice-House and Refrigerator—being for opposite uses—cannot well be combined. In an ice-house everything is arranged for the most perfect preservation of the ice. The value of a refrigerator depends upon the melting of ice, and the best refrigerator is that which allows the ice to melt, and to take its heat from those objects which we wish to cool. To make a cool room in the ice house tends greatly to the waste of the ice. We cool a much larger space than there is any need of, and this cooling is constantly going on, with consequent melting of ice, whether the cool room be full or empty. Those who have had the most experience in this matter, are well persuaded that for the greatest economy in ice, it is far better to have the arrangements for storing and for using the ice separate and distinct, and we think they are right. Let the ice-house be made with the sole view of keeping the ice in the most complete manner, and take from it ice as wanted, to be used in the refrigerator. The size and style of the refrigerator will depend upon the uses to which it is put, and may be a small box or a good-sized room; in either case to be so contrived that there will be little or no melting of the ice from outside heat, but only through abstracting it from the articles placed within to be cooled.

### Hints and Helps For Farmers.

A WAGON LIFTER OR JACK.—“T. G.,” Union Co., Ill., has recently made a wagon lifter, and it

Fig. 3.—HANDY CARRIAGE STEPS.

has proved to be the best one he ever saw. He writes: “Some patented Jacks are practically useless from one defect, namely, they allow the wagon

to start either forward or back, but mine holds it still without a block at each wheel. It is not patented, and all are welcome to the use of it. Figure 1 is the implement complete; the foot piece is 2 by 4 inches, 24 inches long, placed on its edge. The standard, figure 2, is also 2 by 4 inches, and 27 inches long, with a slot in the top 2 by 8 inches to receive the lever. The slot has several holes passing through to adjust the lever to different heights of axle by changing the bolt. The standard is “halved on” to the foot piece and bolted fast. A 1/2-inch iron brace, with a bolt at each end, secures it in an upright position. The lever is 2 by 3 inches, 5 feet long, with a tapering handle, and is bolted 1 foot from the large end. When pressed down it is held by a chain 2 feet long, with a link slipped over one of the 3 headless bolts, as seen in figure 2.

CARRIAGE STEPS.—Whoever lives in the country and regards the comfort of his household will provide some easy means of getting in and out of the family vehicle. There are many kinds of carriage steps or “horse blocks,” as they are sometimes called, the character of which will depend somewhat upon the surroundings. If there is a board fence near by, as is often the case, between the carriage barn and the house, or the house and the street, then steps may be constructed on it after the manner shown in the engraving, figure 3. The exact size will be governed by circumstances, but it should be large enough to be easy to alight from. Its height should be equal to that of the floor of the carriage. Such carriage steps are especially a comfort to lame or aged people, to whom the getting in and out of the vehicle, without some such aid as these steps is the hardest part of the journey.

BAG HOLDERS.—At this season of the year, the grain bags are being filled all over the country,

Fig. 4.—A BAG HOLDER.

and some means of holding them is often thought of, even if the thought does not develop into a design, and the design into a labor-saving implement. Nearly every boy has found the holding of a grain bag to be not only monotonous, but exceedingly tiresome to young arms, and has felt that some sort of a bag holder would be a great relief. There are now a number of patent bag holders in the market, but it is not necessary to go to the expense of one of them, provided a person has carpenters' tools, and a little skill in using them. From time to time, we have given a number of illustrations of these home-made bag holders. Perhaps there is none easier made, and more handy, than the one given in October, 1874, which we reproduce here for the benefit of inquiring grain growers. This holder consists of a broad and heavy bottom board, to give it stability, with an upright piece attached at one side. A pair of diverging arms are fastened to the top of the upright, and are held out horizontally, by a brace which passes from a cross piece between the arms, to notches in the upright. The bag is held in place by having its upper edge slipped over a button, on the second cross-piece, and also turned over the projecting ends of the arms. The dotted line, in the engraving, shows the position of the bag, and how the edge is turned over the button in the rear, and the ends of the horizontal arms in front.

A LOG RAISER.—“F. McL.,” Westmorland Co., Pa., sends a sketch of his Log Raiser, fig. 5, which he describes as follows: Lay a good, stout rail, one end on the log to be raised, letting it extend out at right angles with the log; pass the chain under the log, and hook it around the rail, set the “jack” on the opposite side, and hook the chain to the lever,

Fig. 5.—A LOG RAISER.

as near the ground as convenient. The lever works on two stout pins, the pins being alternately moved up a hole at a time. The method of working the log lifter is evident from the engraving which is given in figure 5.

A CHEAP LEVEL.—The accompanying engraving shows how easily a serviceable Level may be constructed with an ordinary carpenter's square, a short plumb-line, and a sharpened stake. The stake, with a split in the top, is driven into the ground, and the square adjusted as shown in the engraving. For the plumb-line, a string and a piece of lead, or, in an emergency, even a stone, for the plummet, will answer. The line is fastened to the shorter arm of the square, so that it will run close to and parallel with the inner edge of the longer arm. As the two arms of the square are at right angles, when the longer one is perpendicular, as determined by the plumb-line, the shorter one is horizontal or level. Any objects sighted from *a*, along the upper edge to *b*, will be in the same plane, or on the same level. See figure 6.

Fig. 6.—A LEVEL.

A BARN BROOM.—An ordinary house-broom is far too weak for the coarser and harder sweeping of the barn, and, in order to keep the barn floor tidy, a heavy broom is needed. Birch twigs, fastened between strips of boards that are bound together by wire, or, better, by small bolts, will make a broom that will serve a good purpose in the barn. But it is not convenient for all to make their own brooms, and for those who must buy, the

Fig. 7.—A BARN BROOM.

trade supplies a very excellent and durable barn-broom or barn-brush made of strips of rattan, secured in a stout head, to which a long handle is attached at the proper angle. Such a brush is shown in fig. 7; and, when once in use, will be found a most convenient and a durable implement with which to keep the barn floor in good order,

**A Convenient Cottage, Costing \$1,000.**

BY S. B. REED, ARCHITECT.

These designs were prepared to meet the increasing demand for inexpensive and comfortable country houses. The question is frequently asked: "Can a dwelling be constructed for the sum of

The plans here given will be found to excel those referred to in many respects, especially in the amount of accommodation, having *seven* convenient rooms, instead of the usual five, or at most six divisions.... **Exterior** (fig. 1).—The side elevation shows the outside appearance of the house. The body is set at a convenient height from the

Fig. 1.—SIDE ELEVATION OF THE HOUSE.

\$1,000 that will contain all the accommodations and conveniences required by an average-sized family, and withal have an appearance that shall not compromise one's idea of self respect?" The chief difficulty in the way of a satisfactory answer lies in the arbitrary number and character of the rooms required. As a rule, there must be the conventional parlor, dining-room, kitchen, entrances, closets, etc., in the first story, and several chambers above; altogether approximating establishments costing double or treble the estimated amount. Although such demands are perplexing, their number is so large that they can not be ignored. Sev-

ground, the foundation showing 2 feet above the grades. The outlines of the main building are symmetrical and well defined. The roofs are set at an angle of 45°, giving them the prominence they deserve. The gables have a touch of ornamentation, and light chamfer work is put along the frieze, and under the windows, giving a finished appearance. The front and rear Porches are of timber work, also chamfered. In some localities it may be desirable to have more shade in front than is afforded by this porch, in such case a veranda may take its place, crossing the entire front of the house.... **Cellar**.—Height, 6½ feet. In the estimate of cost appended, allowance is made for a cellar under the wing only, which is sufficient in most cases. Others, especially farmers, wanting all the store-room possible, may extend the cellar under the entire building.—[All the cellar-room should be excavated for the sake of good health, even if the room is not otherwise needed.—ED.]—There are two windows, an outside entrance, and a flight of plain stairs leading to the kitchen above.

.... **First Story** (fig. 2).—Height of ceiling, 9 feet. The front entrance is from the porch to a vestibule, and through it to the two principal rooms. The vestibule has a small window at one side, towards which the front door swings in opening, and at the other side sufficient space is allowed for a hat-rack and stand. The Parlor and Dining-room are of equal dimensions, and similar in form, both being octagonal in front, and having a single chimney between them. The parlor has front and side windows, and one closet. The Dining-room, intended as the family living-room, is conveniently arranged, having an open fire-place, three windows, a closet, and direct communication with the front vestibule and rear entry. The Kitchen opens from the rear entry, is fair sized, and well lighted. It has a large fire-place, a pump and sink, two closets, and a stairway to the cellar. The rear entry opens from a covered porch, and is lighted by a small window, and from it a boxed or cottage flight of stairs lead to the second story. It will be observed that there are no superfluous halls, or other waste room, every inch of space being devoted to purposes of real utility.... **Second Story** (fig. 3).—Height of ceiling in the main part, 3 to 8 feet; in the wing, 2 to 7 feet. The roofs, being set at an angle of 45°, are unusually steep, giving increased head-room; then the partitions surrounding the hall are set to add to the height of the vertical walls

where most important. There is a hall, four rooms, and four closets on this floor. The two front chambers have two windows each, and the chimney between them allows for the use of stoves, if required. The two rear rooms serve acceptably as bed-rooms, the larger one having two windows, will accommodate two persons comfortably. The smaller room has a sash-door, through which light passes to the hall.... **Construction**.—The foundations and chimneys are of brick-work. Frame of sawed spruce, siding of pine, "novelty pattern." Roofs of pine shingles; floors of tongued and grooved spruce; windows, four lights each; doors, pine, panelled; plastering, three-coat work; painting, two coats. The following estimate covers the cost of building by this plan. Those requiring the increased veranda, and cellar space suggested, should add \$50. In many localities, suitable stone and sand abound, which may be had for hauling. In such cases, the foundation may be of stone, which, together with the plastering, will cost much less than here calculated.... **Estimate**.—Cost of materials and labor is as given below:

38 yds. Excavation, at 25c. per yd.	\$9 50
11,000 Brick in foundation and chimney, at \$12 per M.	132 00
500 yds. Plastering, at 20c. per yd.	100 00
1,800 ft. Timber, at \$15 per M.	27 00
3 Sills 4x7 in. 30 ft. long.	1 Ridge 2x7 in. 25 ft. long.
3 Sills 4x7 in. 18 ft. long.	1 Ridge 2x7 in. 25 ft. long.
3 Sills 4x7 in. 17 ft. long.	48 Beams 2x6 in. 12 ft. long.
2 Plates 4x6 in. 25 ft. long.	24 Beams 2x7 in. 16 ft. long.
2 Plates 4x6 in. 17 ft. long.	2 Valleys 2x7 16 ft. long.
4 Posts 4x6 in. 13 ft. long.	
300 Wall Strips, at 12c. each	36 00
40 Joist 3x4, at 15c. each	6 00
130 Siding 9½ in., at 25c. each	32 50
Cornice materials	15 00
300 Shingling Lath, at 6c. each	18 00
48 bunches Shingles, at \$1.25 each	60 00
60 ft. Tin Valleys, at 8c. per ft.	4 80
160 Flooring (inside), 9 in. wide, at 28c. each	44 80
30 Flooring (outside), 1½ in. wide, at 25c. each	7 50
2 Cellar Windows, at \$3 each	6 00
15 plain Windows, at \$5.50 each	82 50
1 Corner Window, at \$8; 21 Doors, at \$5 each	113 00
2 Porches, \$25; 2 Stairs, \$16	41 00
5 Mantel Shelves, \$10; Closet finish, \$6	16 00
Nails, Pump, and Sink, \$25; Painting, \$75	100 00
Carrington, \$15; Carpenters' labor, \$125	140 00
Incidentals	4 50
<b>Total</b>	<b>\$1,000 00</b>

**Road Dust** is frequently the most convenient absorbent at the farmer's command; and a few barrels of it, when properly used, will save a large amount of fertilizing material. It is an excellent thing to have in the poultry-house, where the fowls can dust themselves at pleasure, a large box filled with it being the most acceptable shape. The fineness of the road dust makes it of particular value.

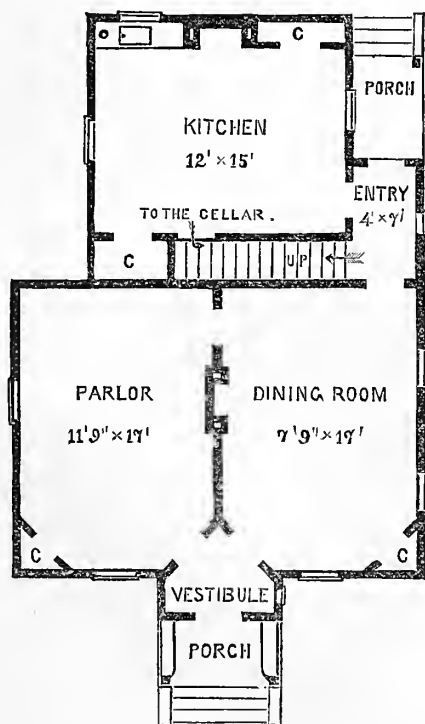

Fig. 2.—PLAN OF FIRST STORY.

eral designs for cottages of this class have been already published in the *American Agriculturist* (see numbers May, 1875; May, 1876; May, 1877, and April, 1878), which may be consulted with profit by those who are considering the subject of building.

Fig. 3.—PLAN OF SECOND STORY.

That containing the most clay is the best absorbent; in fact, a fine sand is of but little use either as an absorbent or deodorizer. A supply of this road dust should be gathered and stored during the first dry spell, before the season closes. There is no better time than the early autumn for the gathering of a quantity of this valuable material.

## Mawah Flowers—A New Cattle Food.

A large tea importing house, Messrs. Billinge & Wetmore, of New York, received from their correspondent in Calcutta a consignment so much out of the usual way that we were consulted as to the disposal of it. The article in question was several tons of Mawha, Mahwa or Mahooa flowers, to be sold as cattle food. The idea of the "effete east"

communication by Mr. E. Lockwood to the Linnean Society, and printed in the 17th volume of the Society's Journal. From this article, Prof. Asa Gray has kindly made for us the following abstract of what relates to the flowers. These fall from the trees in great profusion in March and April. Birds and squirrels feed on them among the branches, and the villagers collect those that fall to the ground in immense abundance. Each tree yields

two or three hundred weight of corollas, and these form a regular and very nourishing article of food for the poorer classes. As the crop never fails, it is very important in times of famine. Much of the surplus in ordinary seasons is distilled into a strong-smelling spirit. Mr. Lockwood closes his account as follows: "But not only are the Mahwa Flowers good for distilling spirits, they are still more useful for feeding cattle. My father, the rector of Kingham, has been feeding his pigs on the Mahwa which I brought home, and Mahwa pork is beginning to be celebrated in this neighborhood.... The extraordinary keeping qualities of Mahwa form also a further recommendation for its introduction into England. Before leaving India, I had a ton shovelled into sacks, and put on board a vessel in Calcutta. They were gathered in April, 1876, and after having been kept for nearly two years, are as good as when first dried. No weevil, apparently, attacks them as they attack grain."—Another account states that so great is the value of these flowers to the natives, that in the expeditions made by the English against troublesome tribes, that they have only to threaten to cut down the Mawah trees to bring the rebellious people to terms. A sample of the flowers as imported shows a soft, sticky mass, with much the appearance of raisins of a poor quality, such as are packed in casks. When soaked in water, the individual corollas swell out, and assume a flattened, globular shape, about as large as an average cranberry, and are found to consist of a very fleshy cup, within which are a great number of anthers. At our suggestion, Messrs. Billinge & Wetmore had an analysis made of this interesting product, and the report of the chemists, Messrs. Krackowizer & Harnish, shows that the flowers contain the remarkable amount of 63.40 per cent of sugar! The other constituents are given as follows:

Without reference to other constituents, this enormous percentage of sugar fully accounts for the value attached to the flowers in India as an article of food, and for their use as a source of spirituous liquors. In a scientific point of view, the Mawah is a most interesting product. It is rarely that we find the flower, the corolla of a plant, to serve any more than as a temporary purpose in protecting the reproductive organs within. For it to secrete more than half its weight of sugar, and thus become an article of economic value, and even of commerce, is most remarkable. The future of the Mawah as an article of trade in this country will, of course, depend upon its cost, and the commercial aspect of the article remains to be developed.

Birds and squirrels feed on them among the branches, and the villagers collect those that fall to the ground in immense abundance. Each tree yields

## Strawberries—New Varieties.

As well expect a spring without a new fashion in bonnets, or, we should say, hats, as a season without new strawberries. There are those who affect to ridicule new varieties, and think that the offering of them is a mere trick of the dealers to make sales. While we think that a variety should not be offered merely because it is new, but should have some point of excellence to commend it, we gladly welcome new kinds that present any claim upon our attention. It is only by the production and testing of new varieties that progress is made. If, among all the new ones offered each year, there could be one worthy of a place on the list of the best, it would be making a great advance. It was worth testing 20 varieties to get the Charles Downing, and what if we put aside 19 others, have we not the Sharpless? There is not, and it is not likely that there ever will be one strawberry that everybody, everywhere, will grow to the exclusion of all others. A few years ago it seemed as if the Wilson would be the universal berry, but now we rarely see it. With some Monarch of the West is in high favor. Our friend Roe says "it should have a place in every home garden;" but though the plants come from Roe, and we know them to be true, in our "home garden," they are as far below the surface as a plow could put them, and there they may do some service as a fertilizer, which is all the use the Monarch can be to us. Observe, this is not a word against the Monarch, for it is a splendid variety in other gardens, but is taken to illustrate the fact that no one variety does well everywhere, and that we must have several good ones.

Among the recent novelties are two seedlings reared in 1876, by Oscar Felton, well known in Philadelphia and vicinity as a successful grower of small fruits for market, and also as an experimenter in the production of new varieties. The two seedlings, the "Orient" and "Satin Gloss," were first brought to our notice in 1878. They were exhibited that year at a show held on the Centennial Grounds, where their merits were recognized by the judges. Knowing the practical character of Mr. Felton's horticulture, he being a producer of fruit and not of plants, the fact that he has adopted these two varieties as his chief reliance for market fruit is stronger testimony as to their quality than anything that might be said about them. We give descriptions and engravings of these new varieties in order to place them on record. As already stated, Mr. Felton is a fruit grower, and he has placed the plants of these varieties in the hands of Gibson & Bennet, who furnish the following descriptions:—

**Orient.**—A seedling of Monarch of the West, and is larger, firmer, and of better color; it yields

NEW STRAWBERRY—THE "ORIENT."

more fruit, which ripens up all at once, and stands up better than that of its parent, berries of the largest size often measuring 6 and 6½ inches in circumference; form roundish-conical; size and shape quite uniform, sometimes a little uneven;

MAWAH FLOWERS (*Bassia latifolia*).

sending food to America, and the idea of feeding cattle, or anything else, upon flowers, are both strange enough to invest the importation with no little interest, and however the matter may result as a commercial enterprise, our readers will no doubt be glad to learn what this article is that is sent a long ocean voyage to feed and fatten our cattle. The Mawah Flowers are produced by *Bassia latifolia*, a tree belonging to the Sapodilla Family or Sapotaceæ of botanists. The trees of this family are found in the tropical parts of both continents, and are noted for affording a variety of useful products. Several tropical fruits are produced by members of this family, others afford oils; the Cow Tree of South America that gives milk, and the tree that yields Gutta Percha, are placed in this family. But we are now interested in one member only, *Bassia latifolia*, which abounds in certain districts in Central India. The tree is described by Roxburgh in his "Plants of the Coast of Coromandel" (1795) as of medium size, with horizontal branches, and smooth leaves 4 to 8 inches long, and half as wide. He figures the flowers as produced in clusters at the ends of the stems, each with a rounded tube, and about 14-parted on the border. The fruit is an inch and a half long, containing one to four seeds, which on expression yield a thick oil used for burning. The wood is very hard and strong, and used by wheelwrights. It is the flowers that have the principal interest for us at present, and pretty much all that is known about these, outside of India, is contained in a

calyx medium; color, a fine scarlet lake, with shiny surface; flesh white, moderately firm; quality excellent. Plant vigorous, productive, the fruit running large to the end. Regarded by Messrs. Gibson & Bennet as the largest and finest berry ever tested in their vicinity. The fruit brought Mr. Felton 40 cts. a quart last spring, and, cultivated side by side with the Sharpless, gave a much larger yield.

THE "SATIN GLOSS" STRAWBERRY.

**Satin Gloss.**—A seedling of the Lady Finger. Fruit medium to large, and in shape somewhat like its parent; calyx very large; color, bright, glossy vermillion, coloring evenly all over; very regular in size and shape; flesh firm, which, with its immense calyx, makes it an excellent shipping berry. Plant exceedingly prolific, continuing long in fruit, and holding its size to the end of the season. Messrs. G. & B. say that this is the most strikingly beautiful fruit of any that they have seen.

### Strawberry Culture—Fall Planting.

In setting out strawberry plants in autumn—that is, ordinary layer plants taken up from the bed in which they have taken root—nothing is gained in point of time over spring planting, so far as hastening the crop is concerned. A field or bed set in April or May, 1881, will bear a full crop in June, 1882. If the same plants were set in September or October, 1880, they would give a crop no sooner. We say "crop," as in either case a few berries may be borne, but none can be depended upon. While the crop is gained no sooner by planting six months or more earlier, there is, except in cold localities where autumn is short and winter long, much to be gained otherwise by fall planting. The soil is still warm and mellow, work is not so driving as in spring, and there is not the fear that a drouth may cut off or injure the plants before they become well established. Those engaged in growing strawberries on a large scale plant at both seasons, but the practice of fall planting is gaining favor. The plants set in autumn have a chance, as gardeners say, to "get hold of the soil," their period of probation being past, they start and grow right on as soon as spring opens. Any apprehended danger from winter thaws and freezing is avoided by the muleh, which all of the plants should have for the best results. Those who would have a crop of strawberries next year can do so by setting out "pot-grown plants." These, as has been explained, are plants from runners which, instead of striking their roots in the soil of the bed, have a small pot of rich earth placed under them, in which they take root. These pot-grown plants may be taken up and set out in August or September, without receiving the least check, and will next spring give a fair or full crop, according to the strength of the plants and time of striking and setting. All the dealers in plants now furnish those that are pot-grown, at a price that can barely cover the cost of the extra labor required to produce them. How far apart? is one of the frequent questions. In field culture the rows should be far enough apart to allow the cultivator to run between them, and this will depend somewhat upon the implement used, three feet being usual, with the plants

a foot apart in the rows. In garden culture, rows two feet apart and a foot between the plants is most common. Other frequent questions are about manure and fertilizers. Large crops of large berries can only be picked by those who have been liberal to the plants. "No manure, no cabbages," is better understood and acted upon than "no manure, no strawberries." We can give no rules for the amount of manure. One successful grower upon being asked how much he used, replied: "All I can get." If about to set a strawberry patch, we should prepare it as the same soil would require for early cabbages, and then put on a little more manure. Wood ashes do wonders on strawberries in the way of making fine, vigorous plants, and guano, if a moderate dressing is given after the fruit is set, will tell at picking time. There is nothing about strawberry culture that should deter whoever has the land from having the fruit in abundance. There is no reason why every farmer's family should not have strawberries, and of the best, and in abundance—yes, three times a day, and no one afraid to pass the saucer the second time. The notion that strawberries can be set only in the spring, has done more than anything else to prevent their general culture. Every one knows how difficult it is upon the farm to get odd jobs done in the spring. This odd job of the strawberry bed can be better done now, this very month, than at any other time. A few bushels from the abundant crop of wheat may well be set aside to pay for the plants. Let them by all means be bought and set this month!

### Currant Culture—"Fay's Prolific."

Of all the small fruits, the currant is the one that the farmer is most likely to cultivate. Like the quince among tree fruits, if put anywhere, and let alone, it is quite sure to produce something, and we oftener see both (the currant and the quince) struggling under neglect than in the enjoyment of proper care and culture. Cultivated as a market fruit, the currant is evidently profitable, as those who have cultivated them for many years quietly add to the extent of their plantations. The experience of our correspondent, "W. C.," given elsewhere, bears directly upon this point. Unlike the strawberry, raspberry, etc., the currant does not demand promptness in picking; a day or two of delay will not ruin the crop, and when sent to market, if not sold the first day, it need not be closed out at a sacrifice, but will appear bright and fresh the next day. In view of these qualities, and the fact that the fruit is always sure of a sale, we wonder that there is so little interest manifested in the currant. New varieties of the strawberry and of the raspberry are brought forward every year, but who has anything to say about a new currant? Those of us who kept the run of fruits thirty or more years ago, can recollect that the Cherry and the Versailles currant were as well recognized as distinct as are the Concord and Delaware grapes. Now our pomologists fail to distinguish the two. We have no doubt that what may now be received from the nurseries as the Cherry and the Versailles are one and the same; but this does not, to our mind, disprove that there were formerly two well-marked varieties known by these names. As the case now stands, the small currants are known as "White" and "Red Dutch;" the large red are

called "Cherry," as that is a better market name, though they are what we formerly knew as "Versailles," and the large white is called "White Grape." So far as the market goes, these have been the varieties for many years past. In this state of affairs, we were much pleased to receive from Geo. S. Josselyn, Fredonia, N. Y., specimens of a new variety of currant called "Fay's Prolific," which appeared to have so many desirable qualities that we inquired as to its history. The variety was produced by Mr. Lincoln Fay, of Portland, Chautauqua Co., N. Y., who has experimented with seedling currants during the past thirty years. He has raised thousands of seedlings, but this is the only one that he regards as a marked improvement over the old kinds. The specimens sent us indicated wonderful productiveness, but this is the quality which appeared to us of less importance than did others, as any currant, under high cultivation, will bear an astonishing crop. In giving an engraving of this new variety, we did not select a specimen to show its great bearing qualities, but with a view to give the size and character of the fruit. The individual berries are of the largest size, the bunches are long, and the fruit holds out of good size from the top to the bottom of the cluster. The bunch has a long stem—i. e., there is a long space of naked stem between the uppermost berry and the attachment to the bush. While this may not appear to be of importance, it makes a vast difference in the picking, as it allows the fruit to be handled without crushing the upper berries, and admits of rapid work. As to the qualities which cannot be shown in an engraving, we may say that the color is good and the flavor most excellent. It has not the intense acidity of some kinds, but is rich and full, and the flesh tender throughout. The

"FAY'S PROLIFIC" CURRANT.

fruit came by express from Buffalo, in excellent order, and on the fifth day after it was shipped was in good eating condition. Being opposed to double-headed names, we wrote to Mr. Josselyn, who had informed us of his intention of placing the

variety on the market, asking him to drop the "Prolific" and simply call it the "Fay Currant," the name it would in a few years receive. To this Mr. J. returned the sufficient answer that there was already a currant introduced by, but not originated by Mr. F. which is locally known as the "Fay," and the addition was necessary to prevent confusion. "Fay's Prolific" appears to possess all the requisites of a first class currant. As to its bearing qualities, Mr. Josselyn thinks that under the same conditions it will produce four to five times as much fruit as the "Cherry." In the specimens sent there might have been more fruit had there been room on the stem to put it. After testing it by the side of other varieties for the past eight years, Mr. Fay has adopted this as a market fruit. In the Buffalo market the variety has already obtained a reputation, and during the past season sold at 15 cts. per quart, when no other variety brought over 10 cts. Upon looking carefully at this variety, and after showing it to good judges, we think that "Fay's Prolific" marks a good step forward in currant culture. To save Mr. Fay the trouble of correspondence, we may state that the entire stock of plants is in the hands of Mr. Josselyn.

### The Small-flowered Lilies.

In describing Kramer's Lily last month, mention was made of the great advance that lily culture has made within the past 20 years. That species, *Lilium Krameri*, represents a class of lilies quite unknown to our gardens a few years ago, and though that appears small by the side of the tall-growing kinds, we now figure one which represents a still smaller set of lilies, and is as small when compared with

THE SMALL-FLOWERED LILY (*Lilium callosum*).

Kramer's Lily as that is dwarfed by the side of the towering *L. auratum*, and the still larger kinds. Indeed the present species seems so far removed from its giant relatives that we look upon it as

something to be nursed and petted, while in fact it is quite as hardy as any. The engraving gives *Lilium callosum* of the natural size, and it will be seen to be even smaller than the "Small-flowered Lily," *Lilium parviflorum*, figured a year or two ago. The botanical name, *callosum*, refers to the fact that the bracts, or upper leaves just below the flowers, are callused, or hardened, and appear of a different texture from the other leaves. The name will translate into "Callused Lily," which, though not a very pleasing name, is sufficiently descriptive. The flower, usually firm in texture, is of a bright scarlet color, of a very lively tint, and the whole aspect of the plant is most pleasing. We have only tried it in out-door culture, but have no doubt that it would be a capital species to force in pots. The native country of this species is Japan, which has so largely enriched our gardens with lilies.

The past summer's experience with lilies has shown the great value of our native species when brought into cultivation. There are three species common throughout the United States, and these vary in a most surprising manner, not only in the size, color, and markings of the flowers, but in their time of blooming. Those who live in the country can make a most showy and interesting collection if they will bring into the garden the bulbs of the various wild lilies they may find. By giving them a rich soil, and leaving them undisturbed, they will increase in size and beauty from year to year.

### The Bag—or Basket—Worm.

Whatever other crops may be short this year, it is not that of insects. In early June so many were the inquiries, with specimens, that we might almost say that the Army Worms marched into our office in procession. In late July there is another procession, but it is now of Bag-Worms or Basket-Worms. These must be in unusual abundance, to judge from the specimens brought and sent by mail, and while they seem to be more abundant on the Arbor-Vitæ, than elsewhere, fruit trees are also troubled. We figured and described the insect in the September number of last year. It is a small, black, and very voracious caterpillar, which makes for itself a bag or covering of bits of the leaves and their foot-stalks of whatever tree it may feed upon. This sack completely hides the caterpillar, as it goes about the trees devouring the leaves, and is thus concealed from birds and other enemies, while it eats and grows. The perfect insect is a small moth. The female undergoes her changes, lays her eggs, and dies within the sack, which she has first taken care to attach securely to a twig, while the male moth quits the sack and flies about. In spring the eggs hatch, and the young insects will come forth, to eat, make other sacks, and continue the round, and when they are numerous the tree is baldly injured. Like other leaf eaters, we have no doubt that Paris Green or London Purple would destroy them, but usually they are not so numerous that hand-picking will not answer. The trouble is that it is only when the trees are partly stripped that the insects are noticed. At their first appearance it is

but a small task to remove them, but when, as in one case, a long Arbor-Vitæ hedge is "full of them," the picking is no small job, but as said before it seems to be the best way to meet them.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### Renovating Old Walls.

A short time ago, we saw the walls of an old house that had just been renovated, and it looked so neat and clean, and the work was evidently so inexpensive, that we sought out the workman, Mr. H. B. Gardner, who had planned and executed the job, and here give his method of doing it. The old walls, before they were taken in hand, were in a very bad state, being rough with loose patches of white-wash, and so much cracked and discolored that the rooms were in a hardly habitable condition.

The method is as follows: "First brush down the walls, to remove the dust and any loose plaster or white-wash, then, having prepared a stencil of the figure desired (figure 1 shows one which may be easily drawn, and cut out of paste-board, or stiff paper), lay the stencil upon the place desired, and with some thick varnish, or paint having some thick or gummy varnish mixed with it, go over the pattern, using a stiff bristle brush. This will leave the pattern clearly defined upon the wall;

Fig. 1.—THE PATTERN.

then immediately sand over the pattern, while the paint is still fresh, using fine, white sand (Rockaway sand), well dried, and free from dirt. The sand will adhere to the 'sticky' paint, and give the pattern a rough appearance. When the paint, holding the sand, is dry, gently dust off all loose particles, and apply a coat of paint over all—roughened pattern, smooth wall, etc." Figure 2 shows the interior of a room with the walls renovated and decorated in the manner above described.

Another plan for making an old wall appear well, is to go all over it with strong glue-size—laying

Fig. 2.—VIEW OF THE ROOM FINISHED.

on the same with a common white-wash brush, and immediately throw sand over the whole before it dries; then, in order to give it the appearance of stone, lay out "stone-work," by simply scratching through the freshly applied rough coat, using a straight edge, and a sharp stick. When all is dry, apply paint, whitewash, or kalsomine over all."

Mr. Gardner recommends the following as an excellent white-wash: "Partly fill a tub with good unslacked lime, (say half a peck), and throw in a pint (dry measure) of finely pulverized glue (comminted glue), then add sufficient water to slake the lime; the heat engendered in the slaking of the lime will melt or cook the glue, and there will be no such thing as 'rubbing off' to the white-wash, when spread upon the wall. The writer would prefer this white-wash to kalsomine, not only on account of economy, but it makes a much cleaner and also a more durable finish."

**The Carpet Beetle (also called "Buffalo Moth.")**—This destructive household pest works

under the edges of the carpets, making holes near the margins. The larva are about three-sixteenths of an inch long, and clothed with dark hairs, those at the tail forming a sort of a pencil. The most effective remedy seems to be the passing of a hot flat iron over a folded sheet, which has been wet and laid along the edges of the carpet. An abundance of steam is thus formed, which, descending, kills the "worms," or moths, as they are generally called. When the insects have infested articles of clothing, these may be put into a tight box, and some benzine poured in, the vapor of which will soon destroy all the moths. The full-grown insect is a beetle, and should be destroyed whenever met with. It is about one-eighth of an inch long, and handsomely marked with scarlet, black, and white.

BY FAITH ROCHESTER.

#### Lessons at Home.

Sometimes it is very inconvenient to send children to school, so that their chance for early education depends upon the parents. Some find it a pleasure to teach their children, while others consider it the hardest kind of work. Much depends upon the disposition of the child, there being a great difference in their natural inclinations. All children really love to learn. That is, they love to know such things as seem to them worth knowing, and often the judgment is a very childish one. Some can not see the use of the letters of the alphabet, or why they should learn the multiplication table, and though you explain their use, they secretly believe that they could get through the world without them, and I sometimes wish that they could. I have taught my children at home a good deal, even when free schools that were called good were close at hand. I found that they could keep up with their classes, or with children of their own age, without spending more than half the time in study that children spend in school, and so they had more time for play and for that domestic education which goes under the head of "helping mother." The hardest thing about it is to train them, especially the ones who want all play, to the habit of going regularly to their lessons, whatever may be the enticements elsewhere. A mother, as usually situated, can not "keep school" while carrying on her household employments. The children must learn to study without her. Rollo's mother (who does not know the Rollo of Jacob Abbott's excellent Rollo books?) managed this matter well. Rollo had already learned to "read, write, and cipher" alone, but was not yet ten years old. His mother gave him a desk in a pleasant corner, where he could keep his books, slate, pens, ink, and papers safe and orderly. She expected him to spend a certain time there every day, while she gave no attention to him. I believe it was two hours. I forget just how the time was divided, but arithmetic and writing were the chief divisions. At the end of his study time, or as soon as convenient, his mother looked over what he had done, explaining to him and questioning him as she saw that he needed, and pointing out his work for the next day. If he could not do the work that came next in order in his arithmetic, or which his mother had marked out for him (she did not tell him "how far to take"), he filled out his arithmetic time by practising examples that he did understand. In the writing hour he wrote whatever he chose, often writing letters to his mother, or father, or Jonas, or cousin Lucy, and sometimes copying. His mother looked this over, giving criticisms and suggestions. They taught him that legibility was the one thing especially needful in writing, and that the particular fashion of the letters was of small account compared with this.

I have been much interested in an account of the revolution in the schools of Quincy, Mass., under the influence of Charles Francis Adams. Few text books or "systems" are used there now. Interesting books of history and science are read instead of "Readers," and from this reading, carefully attended to, are learned, not only the facts communicated by the words read, but grammar, spelling, and rhetoric; besides a greater interest is kept up

### Something About Books.

In teaching our children at home, we can follow suggestions of this kind more fully than teachers in public schools are able to. For children of ten years or more, at least for those who have learned to read with some fluency, there are excellent books that might better be learned by simple reading, *with attention*, than by committing lessons to memory. Miss Hall's Geographies are very good for this purpose. They tell about "Our World" in a very interesting manner. "Little Lucy's Wonderful Globe" is the best book I know of to start an interest in geography among very little ones. It should be read with a globe, if possible, and very good small ones can be got for \$1.50. This book should be read aloud two or three times by mamma, a chapter at a time, pointing out on the globe the country mentioned. Then comes Miss Hall's first book, also read aloud by mamma to the younger ones, but no harm is done if children learn little or no geography until they are old enough to read this book for themselves. It is more important that they should learn to observe things immediately about them—to take an interest in the growth of plants and habits of animals, etc.

I find Felter's First Arithmetic the best I have seen for beginners. The slate-work takes them along easily, with little trouble to me. Then comes (with us) Lydia Nash's Table Book and Rudiments.

I have not been able to give my children at home good desk-room and regular study hours. I often wish I could see some capable person "step into my shoes," and organize my work of various kinds, with a baby (bless it!) under three years of age, always one of the component parts; organize it so that it would move along from day to day with all the ends kept up even, and all done decently and in order. With my very moderate abilities, and lack of financial resources, I have not been able to avoid a considerable "helter-skelter." But I did begin to feel much encouraged last winter when I saw three children go regularly to their lessons soon after breakfast, learning them somehow, in spite of baby's interruptions and mamma's sick days, reciting to each other sometimes, but, somehow, making progress. At our house, the *health* and *happiness* of the children are valued above any mental precocity.

#### Summer House-Keeping Made Easy.

Not every family can keep house with so little heat and labor during the warmest summer months as the one I shall tell about. It is not a system that could be adopted by the farmer's family in the midst of haying and harvest, but even farmers' families may find suggestive aid from this report, and many a small family in town may go and do likewise in some respects.

There are regularly five members in the family, the youngest a year and a half old, he being the only masculine member. To save fire and heat, it is the plan to have only one warm meal a day, the breakfast; but on washing, ironing, and baking days there is usually a warm dinner. Unless there is a fire at noon, the dishes are all washed together once a day—except the goblets and knives—"I thought cold dinners were not healthy," says a neighbor.

That depends chiefly upon the materials of which the dinner is made. If the usual meat and vegetables are replaced by an extra supply of pie and cake, they are decidedly unhealthy. But this family manages otherwise, and less pie and cake are eaten under the present system than formerly. Not a pie has been made or eaten in the house since the summer system went into operation, some months ago, and much less cake and butter are used. (It is not my own table and bill of fare that I am reporting, but I happen to know all about it.) The three women of the family are all workers, and have good appetites, without any particular cravings or sense of lack at present. The body is *nourished* by the food eaten, because it contains good nerve and muscle food. It is palatable, and is eaten with a relish, which leaves no call for salads, condiments, or sweetmeats. Fruit is used, but not extravagantly, seldom more than once a day. It is the most expensive item; acid fruit is much extolled as a medicine, a corrective of bad conditions

of the digestive apparatus. But keep your liver and stomach in order by plain and wholesome fare, and you need not use fruit as a *medicine*, though you may gladly eat it as food, more or less, as the appetite and purse agree. Beefsteak comes in sometimes for breakfast, but usually as a surprise, and then it is remarked "how little meat we eat," and one and another testifies, "I do not miss it at all," or, "I never think of wanting it."

Well, there is always nice white yeast bread and good butter, and sweet milk. There is, besides, some preparation of graham flour or oatmeal, and these form the staple, the most nourishing part of the meal. The oatmeal (from Canada) is always in the form of mush, either hot or cold. It is soaked over night, and cooked for breakfast in a farina kettle. The long soaking makes it cook quicker than otherwise. Various dishes can be prepared from oatmeal, but in the family I mention the mush, eaten simply with good, rich milk (thin, sweet cream is best) is so much liked, that no one has cared to try any other way. Graham is prepared as gems, the flour mixed with buttermilk or sour milk (in either case the proportions, carefully observed, of one level teaspoonful of soda to two teacupfuls of the milk), with very little salt, and a tablespoonful of sugar added. These ingredients are mixed quickly and thoroughly together (the soda dissolved in a little warm water), and baked in gem pans, but the same dough can be baked in a cake tin as a short-cake. The graham is sometimes in the form of yeast bread, and sometimes as mush or graham pudding. Persons often find that oatmeal and graham mush do not agree with them, because they eat so much sugar upon them, and they can hardly believe that these dishes are delicious when eaten simply with good milk, especially if the milk is thin cream! All good mush is nice sliced when cold, and fried on a hot-buttered griddle, and in this way it often comes to my friends' breakfast table—not fried hard, but browned on both sides, eaten with milk, butter, or meat. The various vegetables of the season have their place at the breakfast table or at dinner, on the days when there is a fire at noon for something besides cooking. "Granula," a new-fangled preparation of wheat, very easily prepared, very nourishing, and very good, comes in conveniently quite often. When fresh fruit can not be had, my friends use mostly the best canned fruit, the California pears and peaches being most expensive. This simple style of living was not undertaken for the sake of economizing money, so much as for the sake of saving time and strength and comfort (during a season when a fire is uncomfortable), and also in the interest of "high thinking," for plain living and high thinking are supposed to go together. That may be because plain living (if it is at the same time nourishing) keeps the body in good order, and leaves the mind a fair chance to do good work and have a good time.

#### A Few Small Arts.

**MASHED POTATO.**—To make it light and delicate, beat it with a spoon after you have seasoned it. Mash it well, salting it first. It is often made too salt for my taste, and as I can not take out the salt, it sometimes seems to me it would be quite fair to put in only a little, and those who do not care to taste anything else but salt in their food can add it at their pleasure. Butter is sometimes added when the potato is mashed, but I think thin cream the best of anything, and next to this good sweet milk. Now stir all thoroughly together, beating it well with a large, stiff spoon. The product is something quite superior to the lumpy, poorly seasoned mashed potato often found. A dish may be called "well-seasoned" when only enough good seasoning is used, and that properly put into or upon it.

**TO STONE RAISINS EASILY.**—Pour boiling water over them, and drain it off. This loosens them, and they come out clean and with ease.

**TO PEEL ANY KIND OF FRUIT EASILY.**—Pour boiling water over it, and this loosens the skin.

**TO REMOVE BITTERNESS FROM THE SKINS OF WILD PLUMS.**—Pour boiling water over them, enough to cover them, and remove them quickly before they crack open and lose their juice. Do

not add soda; it does not help a particle, and if the plums do crack open, the soda spoils their flavor. This scalding is done simply to prepare them for being peeled for preserves (if you choose to take that trouble), or to remove the bitterness before the next step in making jelly or preserves.

### Keeping Away from the Mosquitoes.

Perhaps the title should have read—keeping the mosquitoes away from us—but the end is the same,

METHOD OF ADJUSTING THE NETTING.

namely: the escape from the poisonous "bites" of those widely spread pests of summer. We are accustomed to speak of the mosquito, as if there were but one kind; naturalists have named and described over 30 different species, some of which are very rare; some fly only by day, others only at night, but all agree in having blood-thirsty females, while the males neither sing nor sting, but lead innocent lives at play among the flowers. Some of the most savage are only to be found in the damp, dense forests, where they breed in swarms and fill the air with their piping. Fishermen and hunters and their experienced guides would not visit the backwoods without the strong-smelling mixture of tar and oil with which they smear all exposed parts of the body. Only those persons who have gone unprotected into the home of the wild mosquitoes of the forest can know how savage and unrelenting are their wholesale attacks. But it is the escape from the attacks of these pests at our homes that most interests us. Our means of defence may be planned to keep them out of the whole house the entire season, or they may be arranged to protect each individual. In the first method any opening that may allow mosquitoes to enter the house must be provided with some barrier against them. This may be of mosquito netting or fine wire cloth, and placed at every window and door. Only thorough work will answer, and it is poor economy to leave some little-used windows unprovided with screens, as these are the very windows that some one will open, and one open unscreened window makes all the other screens useless—indeed worse than useless, as they will serve to keep the mosquitoes in the house that are let in elsewhere. Screens for the windows are sold at the furnishing and furniture stores; but the majority of our readers will no doubt prefer to make them in the workshop. It is poor economy to put together a temporary makeshift. Our set was well made five years ago, and are apparently good for as many years to come, only that at the most used door has needed some mending of the wire cloth. The frames are of  $\frac{1}{8}$ -inch stuff 2 in. wide, mortised at the corners and put together with glue. The wire cloth is neatly tacked on, and a narrow plain moulding put on to cover the edges. The frames are of just the size of the lower sash. Those edges that come next to the window frames are rabbeted with a  $\frac{1}{16}$ -in. tool, making a square groove of that width and depth. Strips  $\frac{1}{16}$ -in. square are fastened to the window frame with small brads, and the grooves upon the screen-frames slide upon these. Rubbing the pine with burnt umber stain and a coat of shellac-varnish gives a proper finish. The door frames are made rather heavier with a piece of the same stuff across at the middle. They have each a spring that will promptly close them. With these frames put at the windows and doors early in the season, not only do we enjoy freedom from mosquitoes, but from flies, only a very few entering. If mosquitoes are not kept out of the house in this or some similar

manner, then at least the beds should have nets. The nets can be quite simple and cost but very little, or an ample canopy can be made, such as are in use in southern houses. The one we have used with great satisfaction is made of six yards of common white mosquito netting, doubled in the middle, and stitched together on one side, thus forming a double width with a loop or hold at one end where the breadth was turned upon itself. This hood just fits over the head-board and holds one end of the netting securely in place, the other being drawn down and laid over the foot board, securing it, if necessary, with a large pin, and the whole screen is ready. During the day it may be thrown over the head-board or spread ready for use as desired. The cost of the whole protection is 60 cents, or perhaps less. The comfort afforded each night by such a screen is out of all proportion with the cost, and if well cared for will last two or more seasons. The more costly bed canopies are of various styles; some of them are attached to a frame which is so arranged that it can be drawn up to the ceiling by means of a cord and pulley; they can be procured at most house furnishing stores. The beds of children, especially, should be well screened, as their tender flesh is much more attractive to mosquitoes than that of grown people.

### Handy Window Holders.

It is a convenient thing to be able to raise the sash of a window to any desirable height, and then have it securely held at that point, and at the same time be readily let down or moved up higher. All this is made easy by a handy Holder which Edward E. Eyles, Alleghany Co., Pa., has had in use for some time, and who kindly sends a sketch and model. The notched strip of wood is 3½ feet long and one inch wide, and is fastened to the window casing, as shown in figure 1. The key is 4½ inches long and one inch wide, and is placed upon the lower portion of the sash. The key has a small projecting pin by which it can be readily moved. The working of this Holder is very simple; all that is necessary is to push up the window as far as desired, and adjust the key to one of the notches. In lowering the sash the key is slipped out and the window is ready to descend. With the illustration, but little explanation is required.

Fig. 1.—NOTCHED WINDOW HOLDER.

Fig. 2.—THE WINDOW KEY.

down, the upper end of the key must fit into an inverted notch in the casing. Some such convenient device as those mentioned here should be provided for all windows that are frequently opened; it is far better than using a loose stick, or still worse, a hook as a prop for the window sash.

### Household Notes and Queries.

**A JUG RACK.**—The accompanying engraving of a rack for holding a jug, is sent by "J. W. R.," and consists simply of a shelf in which are holes through which the neck of the jug may pass, and the jug be held in an inverted position. The importance of such a rack is evident to any housewife

A DRAIN RACK FOR JUGS.

who has to keep jugs sweet and clean. It is a difficult thing to properly drain a jug without some such arrangement for keeping the mouth downward, and this one, that can be so easily provided, will doubtless be acceptable to many. The water jug for the field, of all other vessels, should be thoroughly drained, and left dry, when not in use, and there is no better way to do this, than to have a small shelf for it like the one here given.

**CORN HUSKS.**—There are a number of important uses to which corn husks can be put in domestic economy. When stripped into shreds by a hatchel, they make excellent material for beds, cushions, etc., as many farmers already know. Another important use for corn husks is in the manufacture of mats for the door. For this, the roughest and heaviest outer husks should be selected, and braided together as tightly as possible. There are two principal kinds of door mats—the plain braid, which is sewn into the desired shape with stout thread, or where a double husk is woven into the plait at every turn-over, the braid being afterwards sewed into the mat as before. In this last, the interwoven double husks project at the upper side, and form a sort of rough brush—the mat when finished, appears as in figure 2. The smooth braid mat is shown in figure 1. A cheaper and more easily made mat is constructed as follows: Take the head of a flour barrel, and bore inch holes into it, close together; insert into each hole a closely rolled bunch of husks, so that the thick ends project a short distance above the board. A wooden

1.—SMOOTH MAT.

Fig. 2.—ROUGH MAT.

peg is driven into the centre of each bunch, to keep it in place. When a mat of this kind becomes worn, it can easily be renewed by replacing the old, worn-out bunches of husks, by new ones.

**WINDOW AWNINGS.**—A shade of some kind for the windows, during the hot months of summer, is almost a necessity. This should be kept in mind by the architect, and in designing the house, provision ought to be made for a permanent shade for the windows, or most of them on the first story, by means of piazzas, verandas, etc. Windows in the upper stories can not be thus protected, and should be provided with temporary screens for them. The difficulty with screens, awnings, etc., has been that the shutting off of the sun's rays, has prevented the means of proper ventilation. In this respect, an outside screen is much better than one placed inside the window, and the appearance of the room is vastly more comfortable. The awning can, and should be, made so that it can be let down from the top a short distance, and then with the upper window sash lowered, a free circulation of air is secured. Instead of nailing the upper side of the awning to the window frame, have it fastened to a wooden bar, or small iron rod, which should be arranged so that it can be drawn up by a cord passing through a small pulley at the top of the window casing, thus securing a free passage of air.

## BOYS &amp; GIRLS' COLUMNS.

## The Doctor's Talks.

Last month I left our regular talks about *Matter*, and its properties, and took up the making and sending up of Balloons. When one is off of the track, it is sometimes easier to stay there than it is to get back again, and as the weather is quite too hot for much exertion, I think we will remain off of the track for another month at least. We have heretofore been talking about *Matter* in its solid form, and though there is much more that might be said, we must get ahead and see what liquids and gases, or

## WATER AND AIR,

have to interest us. These are matters that require more study and thought than either you or I care to give in these mid-summer days, and for the present month we will, by way of variety, talk about the contents of a box that I found upon my table a few mornings ago. The box came, and with it a note which in brief asked—"What is it?" A question that comes almost every day in the year, and with reference to such a variety of things! That is right, young people, when they meet with a thing that they do not understand should ask—"What is it?"—and if you begin to ask this while young, let me assure you that you will never get so old that you will not need to ask the same question of your young days—

## "WHAT IS IT?"

I do not say this to discourage you—far from it—for it is one of the great charms of the study of natural objects, that the whole can never be learned, but there is always some new thing, and the more we know the greater is our desire to learn. But to our box. Upon opening it there were found several curious balls of dry earth, of the shape and size shown in figure 1, as if some one had rolled up mud into pellets and allowed it to dry. An answer to the question—"What is it?" might have been "Mud Balls."

Fig. 1.—THE BALL.

But in such matters we must learn all that such a thing can teach us, and if the outside tells us nothing, the next step is to see what is within. When you come across a thing that is quite new to you, you must learn about it all that your unaided senses will tell you. These balls were plainly made of earth; handling one of them it was found to be much lighter than one of solid earth would be, hence must be hollow; shaking it, something was both felt and heard to rattle, and, of course, there must be something within. "What is it?" comes up again. How shall we know what is inside? "Open it!"—you will say, and that is just what I did. But there are various ways of opening such a ball, and if we do not know what we are to find we must be careful to so open it as not to injure the contents; in this case the way would be to pick off one little piece of the shell after another until the thing within can be seen.

## WHAT WAS WITHIN THE MUD BALL,

is shown in figure 2. And you will at once say, it is an insect of some kind, quietly coiled up, but as you can learn, if you touch it, still alive. An insect in this state of rest, or dormant (meaning sleeping), is called a *pupa* or *chrysalis*, and the case containing it is a *cocoon*. Before we try to learn what insect we have in hand, let us see what we have been doing. You have no doubt read of noted naturalists, some who by studying plants have become eminent botanists, others by the study of rocks, are known as geologists; still others study insects, others

Fig. 2.—INSIDE OF BALL.

give their time to birds, and so on, and such students sometimes become known the world over, each as an eminent naturalist in his line. Now, all that the most learned of these men has done, is just what we have been doing with our mud balls. The most eminent naturalist is only engaged in trying to make the plant, the bird, the rock, the insect answer our every day

## QUESTION, "WHAT IS IT?"

and this he does by examining how it is made, outside and inside. You have no doubt heard of the great naturalist Agassiz, who died a few years ago. I once heard some one express to him wonder at some of his discoveries. Agassiz said: "I look at ze thing, I put down what I see. You look at ze thing and see it ze sam', and zat is all."—This side talk is to impress upon you the fact that there is nothing about either branch of Natural Science as it is called, to prevent any country boy or girl from studying it; the objects are everywhere around them, and they have only to examine them within

and without, using carefully their eyes and other senses, to find an endless source of instruction. Now we

## GO BACK TO OUR MUD BALL

The quiet insect is there, and we may go back and learn what it was before it came there, or go on to see what will become of it. As we have it in its earthen cocoon, it will be as well to follow it and see what it will do next "Zip, zit, boom"—are the sounds as you read at evening by the lamp, and you at once know—at least if you live in the country—that a May-bug, or June-bug, or a Dor-bug is in the room. Some nervous people may be afraid of it, but you know it to be perfectly harmless, as far as any harm it can do to you goes, so you watch where it falls, pick it up and put it out of the window—but as you put it out it is well to give it such a squeeze between the thumb and finger that it will never fly or move again. Some may not know this "bug," as it is called, but beetle as it properly is, so I give its portrait in figure 3, as the perfect state of what is shown in the imperfect state in figure 2. A few of these beetles come into the house, attracted by the light, but in seasons when they are abundant, you were to take a lamp out into the orchard, or where there are other trees, you would be

3.—THE BEETLE.

astonished at the numbers that would come about, and sometimes they are found at work in the trees in such numbers that they may be shaken down and caught by the painful. All beetles are not troublesome in their perfect, or winged state, but this one feeds upon leaves, and sometimes does much damage by stripping the trees of their foliage. This is one reason why I advised you to give the one caught indoors a sharp pinch—to prevent it from doing any more mischief itself, but especially prevent the harm its progeny might do, as each female beetle will in time enter the ground and there

## LAY 40 OR 50 EGGS,

which soon hatch and produce small, white grubs—or "worms" as they are commonly called—but the proper name for these and all other insects in this state is *larva*. These *larvæ* (plural of larva) go on feeding for some three years upon what they find in the earth. At the proper time, they form the mud balls with which I began their story, and at length come out as beetles. Before I say anything about the ways of the grub or larva, I want

Fig. 4.—THE WHITE GRUB.

to call your attention especially to these changes, as they are what happen, in one way or another, to all insects. I have here given in brief the different changes of the June-bug, and as I find that many grown persons do not know that insects take on these different forms, and the order in which they follow one another, I wish to impress upon you "the order of their going." We have first the *egg*, second the *larva*, which may be known as grub, maggot, caterpillar, and oftener under the general term of "worm." This, in making its growth, changes its skin several times, and at last becomes a *pupa*, in which state it is usually quiet for awhile, and looks quite unlike the larva from which it was formed. In some cases the pupa is formed underground, but in many others it is covered in a cocoon of silk, and attached to trees, etc. Sooner or later, the pupa bursts its covering, and the perfect insect or *imago* appears. In this case a beetle, in others a butterfly or moth, or it is a two-winged or a four-winged fly, or some other insect. I can not now speak of the different kinds of insects, but merely say that in all we find these different states, and these changes more or less complete.

REMEMBER THAT, EGG, LARVA, PUPA, AND IMAGO, or perfect insect, is the order of these wonderful changes. Now we come back to the larva of our June-bug; small at first, it feeds upon the minute roots of grasses, and is not noticed, but in time it gets large enough to be known as the White Grub, and (fig. 4) is as large as your little finger. In this state it is one of the farmers' worst enemies, as it eats the roots of nearly every plant it meets. I have known it to take the roots of young fruit trees as large as your little finger, cutting them square across; it will make great holes in the potatoes; it will get into the strawberry patch, and plant after plant in a row will die, its roots all cut off, before the grower finds out the trouble. I can not tell you all the mischief it does, but perhaps its worst work is in grass lands, quite ruining the finest pastures. One of my friends near Boston has a place noted for its many acres of beautiful lawn. A few years ago, he saw his fine green turf turn to brown, and found his grass had no roots, but he could roll up the sod as if it were a carpet. He had to sow his lawn anew, and I happened there at the time when he had a dozen or more men who picked up these grubs by the

bushel. But I can not tell you more about the damage this grub does. Like other insects, it

## HAS ITS NATURAL ENEMIES.

Other insects prey upon it, and crows, often accused of doing mischief when really doing a good work, take many, as do skunks, and it is said that hogs will root for and kill them. But the enemy that is likely to be of the greatest help in keeping the grub in check, is not an animal, but a plant! Several years ago we had sent us some white grubs, each bearing one or two enormous

Fig. 5.—FUNGUS ON WHITE GRUB.

horns, as shown in fig. 5. An examination showed these to be plants which were growing upon the grub, in fact planted in and feeding upon them just as other plants grow in and feed upon the soil. This plant sometimes attacks the grubs in vast numbers, so that nearly every insect is thus ornamented. The plant is a kind of *fungus*, the family of plants to which the toadstools as well as the mildews, rusts, and blights belong. This gives you a glimpse of one of the wonderful relations between animal life and plant life. Experiments are being made with the hope that this fungus may be made useful in destroying the white grub. Instances in which insects live upon and injure plants are common enough, but for a plant to live upon and destroy an insect—for a white grub that has these plants attached to it must soon die—is quite unusual.

## THE DOCTOR.

A Picture Puzzle.—The scene which is here given is one made up of rocks, trees, and the sea. There is nothing particularly strange in the way in which the

rocks are arranged to make the cliff, and why shouldn't the trees grow just as they are represented? The picture is then, as far as the trees, rocks, and sea, are concerned, a natural one. But do you see anything more than has been mentioned? This matter must be left to each one to find out. When once seen—and it is liable to be seen at once—it is always there as plain as a nose on a man's, or anybody else's face whenever one looks at the picture.

## Our Puzzle-Box.

## CROSS-WORD.

My first is in schooner but not in brig,  
My next is in whisker but not in wig,  
My third is in elbow but not in knee,  
My fourth is in meadow but not in lea,  
My fifth is in baton but not in stick,  
My sixth is in mortar but not in brick,  
My seventh is in always but not in now,  
My eighth is in forehead but not in brow,  
My ninth is in album but not in book,  
My tenth is in scullion but not in cook.  
The answer you'll find if you properly seek,  
It is something that happens just once a week.

C. F. W.

## ANAGRAMS.

- |                     |                     |
|---------------------|---------------------|
| 1. Rail O big chap! | 6. A mere tune.     |
| 2. Licks a berry.   | 7. I merit a slip.  |
| 3. Mud in soil.     | 8. Be tanning.      |
| 4. A. C. anchored.  | 9. Unkind grate.    |
| 5. Such of Dave.    | 10. Ann wears bine. |

## TRANSITIONS.

(In the following puzzles you are to change only one letter at a time until you resolve the first word into the second. For instance, to change *cat* into *dog*, do it thus—*cat*, *cot*, *dog*. Some might do it thus—*cat*, *bat*, *bag*, *bog*, *dog*; but the former is the more creditable, having the fewer changes. It will add to the interest, if

OPPOSITES (*Geographical*).—1. Lapland. 2. Iowa. 3. Sleepy Hollow. 4. Jackson. 5. Sicily. 6. Providence. 7. America. 8. Annapolis.

Pr.—There was once a doctor who, when asked what was good for mosquitoes, wrote back, "How do you suppose I can tell unless I know what ails the mosquito."

NUMERICAL ENIGMAS.—1. Be sure you are right, then go ahead. 2. Westmoreland County.

A PICTORIAL ANAGRAM PROVERB PUZZLE.

The answer is a proverb of seven words. Each numeral under the pictures represents a letter in that word of the proverb. Get your slate, or piece of paper, and write down the first seven numerals in a row. Take, for example, the "5" above; put the F under figure 2, the A under figure 3, and the N under figure 5. Write down the names of the other things represented, letter by letter, under the given numerals, in the same way, until you have put them all down; then arrange the letters to form the right word, until you have the 7 words necessary to complete the proverb.

several of you take the same words to metamorphose, and see who will accomplish it first, and in the fewest moves.)

1. Change June to July.
  2. Change two to six.
  3. Change came to went.
  4. Change mine to bond.
  5. Change pool to lake.
  6. Change book to play.
- (and any other changes that may suggest themselves to you. Of course you are not allowed to coin words, but must use only such as are to be found in the English dictionary.)

AUNT SUE.

## POSITIVES AND COMPARATIVES.

(Examples.—Positive, an animal; comparative, fresher. *Gnu*, never. Positive, a fastening; comparative, part of a wheel. *The*, tire.)

1. Positive, to divide; comparative, a city.
2. Part of a dress-maker's small trimmings—an animal.
3. A pronoun—a period of time.
4. A blow—an article of apparel.
5. What many object to take—a support.
6. An adjective—a kitchen utensil.

BESSIE.

## DECAPITATIONS.

1. Behead a word sometimes sad and sometimes glad, and leave a number.
2. Behead a breath and leave a reptile.
3. Behead a certain article of food and leave what you do with it.

## NUMERICAL ENIGMA.

I am composed of 32 letters:  
My 1, 11, 24, 20, 25, 27, 23, 8, is a munnery or monastery.  
My 6, 8, 2, 9, 16, is to overwhelm.  
My 13, 5, 3, 7, is a kind of tooth.  
My 4, 14, 10, 31, 29, 30, is to slope.  
My 32, 15, 12, 23, is to bark.  
My 17, 26, 8, 15, is dismal.  
My 19, 18, 21, 30, is to yield.  
My 6, 28, 23, is to plunge.  
My whole is one of Baron Rothschild's maxims, and contains good advice.

## DOUBLE ACROSTIC.

1. A dialect.
  2. A goddess.
  3. A flowering pot.
  4. A Shakespearean character.
  5. A West India island.
  6. A mixture or medley.
  7. A flag or banner.
- The initials and initials name two of Scott's characters.

ISOLA.

## CHARADES.

1. My first is a mold, my second an article, my third a trap; my whole is often used by ballet dancers.
2. My first is under, my second is a conjunction, my third is a noise, my fourth we all do; my whole is subject.

GUILIELMUS.

## ANSWERS TO PUZZLES IN THE JULY NUMBER.

DROP-LETTER WORDS.—1. Abstemious. 2. Topography. 3. Progenitor. 4. Investment. 5. Fraternity. 6. Curmudgeon. 7. Seamstress. 8. Remunerate.

MIXED PROVERBS.—Where there's a will there's a way. Necessity is the mother of invention. Many hands make light work. Time and tide wait for no man. Brevity is the soul of wit.

CHANGED HEADS.—1. Blight, night, light, sight, wight, right, right, tight, eight, night.

METAGRAM.—SHADE: in which may be found the words—has, had, dash; shad, head, sea, ash; he, she; as; sad; a; ah!

CROSS-WORD.—Pinchbeck.

And how he could eat! He never had enough; and I verily believe that if I had a bushel of flies to give him he would have eaten them, or died in the attempt. He was a piggish little fellow anyway, never being entirely satisfied with what he received from our hands.

The scientific title of my little pet, that is, the name bestowed upon it by naturalists, is "*Phrynosoma cornutum*," and I thought to call him by the name of "Tappy," for short; but the children at once raised a great cry, declaring that it was an "ugly name," and thereupon dubbed him "Dicky" on the spot, and "Dicky" he was ever after. I said he was homely, and so he was; but after we had him a little while we did not think so. How he looked you can know from the engraving; you have only to imagine a creature like that, about the length and width of your hand, that is, supposing you are eight or ten years old, and you may have some idea of our "Dieky." His flat, toadish sort of a body he could blow up and swell out to twice or three times its usual size when he liked—as the frog in the fable did when he wanted to be as big as an ox. He was covered with a lot of little spines or thorns, extending down his back, along his sides, and on to the tail. Those upon the edges of the body were regular prickles like saw teeth; and four or five little horns projected back of his head on the nape of the neck, looking as if he wore a collar of leather stuck full of carpet tacks. His color was not unlike that of a common toad, with a grayish-yellowish mottled belly. But he could change these colors at will, seemingly, to look like what he might be lying on, much the same as does his cousin the chameleon. When on my desk, he would manage somehow, especially when flies came sailing by, to look like the dark-green cloth that covers it; and once when placed on the russet-colored plush of the buggy seat, he looked so much like it, that on one occasion I did not notice him, and nearly sat down on him.

"Dicky" did not like dead flies, and would not touch them unless very hungry, and not always then. He preferred to catch them for himself, though he would frequently take them from my fingers. He would be on the window seat for hours, enjoying the warm sun, perfectly quiet until some fly came buzzing close by, when he would open his sleepy eyes, and with a quick dart of his tongue gather the insect in. If the wind should stir dead flies, or if I breathed upon them, he seemed to think them alive, and they would disappear down his little throat one by one with amazing rapidity. He would eat some spiders, others again he would not. A "Daddy, Long-legs," or "Father Gray-beard," he specially disliked; and if one were placed before him, he would puff out his body, arch up his tail, and then back off, at the same time opening his mouth and gaping as if very much frightened; and if it insisted on going towards him, he would shuffle off as fast as his stumpy legs could carry him. Another thing, he did not breathe as most animals do, in a regular manner, but like turtles, taking the air into his mouth and swallowing it, where it could be conveyed into the lungs at pleasure. When the cold weather came, "Dicky" was inclined to go to sleep, to *hybernate*, as it is called, so we rolled him up in some cotton and laid him away in his box on a shelf in a dark closet; and though he was frequently taken down and examined, he never showed any signs of life until the following spring, except once when he was left a few moments in a very hot room. Well, as hinted before, the dog killed

THE SO-CALLED "HORNED TOAD" OF TEXAS.

I took him from his box and hid him on my desk. Certainly he must have known that I never made sport of his ugliness; moreover it was I that always brought him food. It was amusing to see him put out his cunning little tongue for a fly with a quick little dart-like movement, and funnier still to see it disappear with a gulp down his throat, after which he would wink and blink his eyes with satisfaction; then he would raise his head, twinkle his eyes and wiggle his tail, as much as to say, "Some more of the same sort if you please, sir!"

him, after we had him a little over a year. The children cried and vowed they would have nothing to do with "Hark" any more, and even mamma looked teary about the eyes. I don't know but I could have cried myself with but little effort. In his native home in Texas our "Dicky" would doubtless have enjoyed himself less, because there he would have hid among stones and rocks to escape from danger; but he might have had a longer life and a less eventful one than it was. [We have several times received specimens of these toads from our readers

in Texas, which came "alive and well" in little boxes by mail. Any of our young readers having friends in Texas and desiring such strange-looking "pets," can most likely get some of them by writing for them.—Eds.]

### Another of the 'Ologies.

The Boys and Girls have not had an 'Ology for some time—not since we spoke of Zoölogy in the May number. We have a great many kinds of fruit sent to us to name, that is, Mr. A. has a peach that he does not know the name of—the label has been lost or something, or Mr. B. has, as he may think, a new kind of pear, or Mrs. C. a fine grape which she wishes us to see and taste, or Miss D. has "a tree of her own which has borne some fruit for the first time," or even Master E. sends us a little box all nicely packed full of choice plums which he wishes us to eat, with his compliments. Now, all this is *Pomological* and the questions of this sort in regard to fruits are questions in *Pomology*. This was the first 'Ology that we had.—But not all the boxes that come contain fruits. There are a good many that, when opened, reveal some great beetle, some curious colored "worm" or destructive insect that may be eating the tomato vine, currant bush, or, as was the case with the army worm a few weeks ago, making great havoc with the crops generally. All these questions about insects come under the head of *Entomology*—a Greek word which means a telling all about insects—that part of knowledge which has to do with those little six-legged animals, like fleas, June bugs, butterflies, etc., which we call insects. When one of these little boxes comes and we find upon opening it that it contains a bug or a beetle—there is a difference between a bug and a beetle—or a moth, etc., that we are not familiar with, then we turn to a number of books in which these various—yes thousands of—insects are described, explained and pictured, and find the one that is like the one sent. All this is looking the insect up in the books on *Entomology*. An *Entomologist* is one that has made a study of insects and become acquainted with the world of bugs and butterflies. This is well for every boy and girl to do as much as possible.—In this way you will understand *Entomology*, or the science of insects; in fact, become an *Entomologist*.

**At the Fair.**—As we look over the premium lists of the various State, County, Town and other Fairs that are now coming to our office, we frequently find a "Youth's Department," in which prizes are offered for various kinds of things that can be made or raised by children. This is as it should be; and for the sake of the boys and girls we say to all—Something should be done for the children at the fairs—so that they, as well as their fathers and mothers, may be exhibitors. But if your fair has no Children's Department you ought to go all the same, and see all the fine things that grown folks bring. It is not best to go entirely for the fun of the thing, and spend all the time in the side shows that are very ready to take up your time and your money. If you are a boy it may be that you will be the most interested in the cattle—the fine steers, etc., or it may be that the poultry will be the most attractive, and by spending an hour or so there you may learn something about the different breeds that will be of use at home. The girls will naturally enjoy the display of household goods, the fine quilting, embroidery, wax work, flowers, etc. The fair is a great place for gaining information if the time there is rightly employed.

### The Tired Nut-Gatherers.

When I was a boy! What a world of things come into my mind at the thought contained in those five short words—"When I was a boy." How they carry me back to the happy days of my childhood when everything was new to me, because I was new to the world. To the time when my tough, bare feet were ready to go anywhere and for anything that my childish fancy might suggest was worth the while. No city life was mine; the fields of my early days were the green ones of the

chores to do around the house, no errands to the village or the neighbors—Saturday afternoons were not holidays to them, because, as we thought, the squirrel's life was a kind of perpetual holiday. One year the squirrels were uncommonly thick, and the nuts were not so abundant as usual, both of which facts combined to make our showing for a good supply of winter nuts a poor one. The chattering nut-gatherers seemed to come in swarms, and the woods resounded to the hunter's gun; but with little effect upon the numbers of the fur-bearing, nut-loving animals. All this while the nuts were growing scarce,

and George and I knew it, as we did our part of the farm work—carrying a plow point to the back field, or helping to build a fence along the wood lot. It was aggravating to us to see them so saucy in their way of taking off our nuts. At last, Saturday afternoon came, and we were bound to do what we could to drive the squirrels from the wood lot, and at the same time get all the nuts we could for ourselves. It was a hard day's work, but we felt that it was our last chance, and we went into the fight, so to speak, with a will. If we could get but few nuts we would at least make it troublesome for the squirrels to add much to their stores. We had a big time, but we would not say we had the worst of the bargain. To follow a running squirrel who has the highway of the fence, or the tall tree tops, when you are obliged to dodge around trees and stumble over stumps and stones, is not an easy matter; but in the excitement of the chase it can be done for hours without a thought of getting tired. This was our experience; but in the long run the squirrels have the best of it, and though "driven from the field" they can claim a sort of victory, because they come out ahead. All that afternoon we ran and climbed—rushing through thickets and over brush fences, through deep ravines and up hillsides, following first one squirrel and then another, until it was lost in the dense foliage of a tall tree, or safe at home in some hollow log. As the sun got low in the western sky we found ourselves

THE TIRED NUT-GATHERERS AT REST AFTER THEIR LONG CHASE.

country, and perhaps therefore the more interesting in memory. Like most boys, I had a mate with whom I spent most of my play hours, sharing our pleasures and pains together—helping each other into petty troubles, and as eagerly helping each other out. If the sheep were to be washed, George and I were together, and the lambs had their wool made perhaps a little whiter by our squeezing, though fun, rather than clean wool, was what we were after. When the steers were old enough for the yoke, it took both of us to manage them. The water-melons that George had cared for in his garden were mine, and the peaches and pears in our orchard were his by the same right. It was silently understood between us that our things were in common—a no uncommon thing with boys, and girls too, that are mated. One of the most pleasant times in the whole year was when the nuts were ripening on the trees. To gather a fine lot of them for the long winter evenings was our ambition, as it is of nearly every boy that I have ever met. On this one point squirrels and boys agree, and at nutting time, if not the whole year, these two kinds of nut-gatherers are not in love with each other. That which troubled us most was the earliness in the season with which the squirrels opened their work. It seemed as if they knew that in order to get their winter's supply of food, they must get into the trees before we did. Besides, they had their whole time from early morning to late evening, and every day in the week, Sundays not excepted. They had no water to carry to the thirsty workmen; they had no

far from home in the thickness of the forest. We had chased a little noisy nut-gatherer to his storehouse, and were paid for our trouble in the hat full of nuts which we raked from the end of an old hollow basswood log. We felt tired, and sat down to rest and have a taste of the fruits of our pursuit. We found a good place near some rocks, upon the side of an open ravine, and with a small stone began to crack and eat some nuts. We did not crack and eat long before we fell asleep, and went over again in our dreams the exploits of the day. The moon was well up when we awoke, and by its pale light two tired boys—though somewhat rested by the long nap upon the mossy stones—found their way home and went quietly to bed. The other day we saw a picture made by Messrs. Harroun and Bierstadt, that reminded me so much of how George and I must have looked as we rested on the mossy rocks, that I have had our artist engrave it for the boys and girls of the great *American Agriculturist Family*. You can not but enjoy the nap of the Tired Nut-Gatherers, as it is taken in each other's arms upon the rocky edge. A penny for their thoughts you may say, but no money will buy their dreams; they were ours to keep. I can not go farther with our squirrel hunt—and perhaps you may think we went far enough with it as it is told—but must leave you, hoping that fewer squirrels and more nuts may be your good fortune—that you may be less tired at the close of your nutting afternoon, and have less holes in your clothes than did George and your UNCLE HAL.

COVER-SEED RAISERS and Threshermen, don't neglect to read "Farmers' Report on Clover Hullers," which will be found in another column of this paper.

## DUTCH BULBOUS ROOTS.

J. M. THORBURN & CO.,

15 John St., NEW YORK.

Beg to announce that their new Descriptive Catalogue of Dutch Bulbs for the Autumn of 1880 is ready for mailing to applicants.

Parents Should Ask for the

(A.S.T.C.)

## BLACK TIP

In place of the metal, as it WILL WEAR AS WELL, and is intended to take its place

UPON CHILDREN'S SHOES.

**USEFUL ARTICLES**  
AND

**SENT FREE**

On Receipt of a 3-Cent Stamp to all who Mention the American Agriculturist.  
**LONDON NEEDLE CO.,**  
22, 24 & 26 4th Ave., New York.

ASK YOUR WATCHMAKER FOR

**AND NOT WEAR OUT.**  
By mail 30c.—AUTOMATIC Eye Glass Holder, by mail 25c.—Birch's Pat. Key Ring, 10c.—Circulars free.  
**J. S. BIRCH & CO., 38 Dey St., N. Y.**

**Improvement for 1880.**  
**THE SAFETY HOT BLAST OIL STOVE.**  
Does not heat the house. Perfect for all kinds of Cooking and Heating Irons. Always ready and reliable. The most satisfactory Stove made and the Cheapest. Send for circulars.  
**The Whitney Mfg Co.,**  
113 CHESTNUT ST., PHILADELPHIA.

1880 Established 34 Years, 1880

Both designs on each label.

Salutary the same.

**NONE BETTER MADE! TRY IT!**

Office, 11 Old Slip, New York. Factories, Harlem.

## WHEEL CHAIRS

Exclusively.—ALL Styles and Sizes for Invalids and Cripples

Self-propulsion by use of hands only, in street or house. Comfort, durability, and ease of movement unequalled. Patentee and Maker of the "Rolling Chairs" pushed about at the Centennial. For Illustrated Catalogue send stamp and mention *American Agriculturist*.  
**HERBERT S. SMITH, 32 Platt St., New York.**

## Steam - Engines.

More effective and more complete, and more readily adapted to the various mechanical and agricultural uses than any other in the market. Practical improvements accumulated from twenty years' manufacturing experience, with reputation maintained and success established. Send for Circulars descriptive of all containing testimonials concerning our **PORTABLE and AGRICULTURAL STEAM-ENGINES.**  
**WOOD, TABER & MORSE, Eaton, Madison Co., N. Y.**

## COLUMBIA BICYCLE.

Bicycle riding is unsurpassed as a method of traveling, whether for speed, sport, or the renewal of health. No horse can compare with the bicycle for endurance, no other pastime is half so fascinating, and the exercise is recommended by the medical profession as being most conducive to health. Appleyard rode 100 miles in 7 hours, over a common turnpike road, and Waller has accomplished 1,400 miles in 6 days. Send 3c. stamp for 24-page catalogue, containing price lists and full information, or 10c. for catalogue and copy of "The Bicycling World."

**THE POPE MFG CO.,**  
No. 101 Summer St.,  
Boston, Mass.

## H.W. JOHNS' ASBESTOS LIQUID PAINTS

Are the purest, finest, richest, most durable and economical paints ever made for structural purposes. See editorial article in April No., 1879, of *Am. Agriculturist*. Samples of colors and Descriptive Price Lists free by mail.

**H. W. JOHNS' MFG Co., 87 Maiden Lane, N. Y.**

**CORN HUSKER.**  
No cold or sore fingers, if used with gloves or mittens. Can be used without gloves or mittens, if desired. Will last a lifetime. Taken 6 Premiums. One sample 25 cts.; two for 45 cts.; 5 for \$1.00.  
**CITY NOVELTY CO.,**  
108 S. 5th St., Philadelphia, Pa.

Send stamp for Catalogue.

Rifles, Shot Guns, Revolvers, sent o. o. d. for examination

COMPLETE FOR \$2.25.

## NEW IMPROVED FRET SAW.

The Saw in position, ready for you to go to work, and make money, or beautify the house.

Every home, however humble or magnificent, is more beautiful if adorned with brackets and other work produced by home hands. Hundreds of thousands of such homes now exist, where only the slow and tedious hand-frame fret saws have been available. More recently the foot-pedal and multiplying wheels have come into use, and the increasing demand has tended to cheapness and improvement. We are now happy to announce another LARGE ADVANCE IN

Perfection, Cheapness, and Portability,

by which are secured stronger, better working machines; a material reduction in price, and a great saving in cost of carriage or delivery, as well as in storage room when not in use, with sundry other improvements and advantages.—All the above are secured in this new saw.

Price complete, boxed, ready for shipment, \$2.25.

**ORANGE JUDD CO., Sole General Agents,**  
245 Broadway, New York.

Send for our complete Price List of Games and Toys.

## AGENTS WANTED to Sell the NEW BOOK, FARMING FOR PROFIT

**TELLS HOW TO**  
Cultivate all the Farm Crops in the Best Manner; Breed, Feed and Care for Stock; Grow Fruit; Manage Farm Business; Make Happy Homes, and **MAKE MONEY ON THE FARM.**  
Every Farmer should have a copy. 360 Pages. 140 Illustrations. Send for circulars to **J. C. McCURDY & CO., Philadelphia, Pa.**

## Wesleyan University, MIDDLETOWN, CONN.

Three four-year courses—Classical, Latin-Scientific, and Scientific. Large range of elective studies in each course. Fine Museum, Laboratory and Observatory. Post-graduate courses in Literature and Science. No preparatory or professional courses. Free Scholarships when needed by worthy students.

Entrance Examination Sept. 9th.  
For Catalogue address **WM. NORTH RICE,**  
Secretary of Faculty.

**LADIES AND STORE-KEEPERS**—You can get L. Choice Goods, cheap, by writing us an order on a Postal Card for our Price List, which enables you to order goods by mail the best way, and see the many kinds of Merchandise we keep for sale at surprisingly low prices. We send samples of Hamburgs, Laces, Ribbons, Fringes, etc., if requested. We sell Wholesale and Retail for cash down. A new combination system which we have just started enables us to quote very close prices. We have \$1, \$2, and \$3 packages of notions which can not be bought for twice the money elsewhere, all wanted in every family. Money returned if not satisfactory for any purchase.  
**HOUGHTON & DUTTON,**  
55 Tremont St., Boston, Mass.

## Scribner's Lumber & Log-Book.

NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and plank, by Boyles' Rule, cubical contents of square and round timber, stave and heading bolt tables, wages, rent, board, capacity of cisterns, cordwood tables, interest, etc. Standard Book throughout United States and Canada.

Ask your bookseller for it, or one sent by me for 35 cents, post-paid.

**G. W. FISHER,**

P. O. Box 238, Rochester, N. Y.

**9th JUST READY.**  
CLEARANCE CATALOGUE of Illustrated, Standard, and Popular Books offered at 30 to 60 per cent discount from published prices. Sent free to any address. Send postal note to **ESTES & LATIMER,** 301 to 305 Washington St. (opposite Old South), Boston, Mass.

**HAYWARD'S COMMUNION WINE.**  
The Pure Juice of the Grape Unfermented. Unequalled in Purity, Color, and Flavor. Send for Circular. Manufactured by **J. P. HAYWARD, Ashby, Mass.**

## 12,000 IN USE.

American Vegetable Slicer, for cutting beets, turnips, etc., for feeding stock. Cuts one bushel per minute. Price, \$12. Send for circular.

**AGRICULTURAL WORKS, Millport, N. Y.**

**ELGIN WATCHES.**  
All styles, Gold, Silver and Nickel, \$6.00 to \$150. Chains, etc., sent C. O. D., to be examined. Write for Catalogue to **Standard American Watch Co., Pittsburgh, Pa.**

## VACATION READING.

**CONCORD GUIDE BOOK.** Edited by Geo. B. Bartlett. Cloth, \$1.00; paper, 50 cents. Containing descriptions and illustrations of all points of Historical and Literary Interest in and about the old town of Concord, Mass.

**BARK CABIN ON KEARSARGE.** *Out of School Series.* By EDWARD A. RAND. Price, 30 cts. Mingled with the adventures of the party are realistic descriptions of the scenery about Mt. Kearsarge.

**ONE CENT.** *Out of School Series.* By ROSE HAWTHORN LATHROP, and other favorite authors. Price, 30 cents. As bright and jolly a collection of stories as any boy or girl would wish to read, full of illustrations and brimming over with fun and frolic.

**WHAT SHE SAID AND WHAT SHE MEANT.** *Idle Hour Series.* By PANSY. Price, 5 cents. This popular series is enriched with another volume from the facile pen of Pansy, who always has some important lesson to teach or principle to illustrate.

**PEOPLE WHO HAVEN'T TIME AND CAN'T AFFORD IT.** *Idle Hour Series.* By PANSY. Price, 5 cents. The lesson to be drawn from this story is that when one resolutely sets about a good work, success is sure if backed by persistence, courage, and perseverance.

**HOW TWO GIRLS TRIED FARMING.** *Idle Hour Series.* By DOROTHEA ALICE SHEPHERD. Price, 50 cents. A piquant narrative of an actual experience.

**POOR PAPA.** *Idle Hour Series.* By MARY W. FORTER. Price, 50 cents. Pronounced the most brilliant and entertaining SUMMER BOOK issued for years.

**WIDE AWAKE,** for September, has special attractions. 20 cents a number. \$2.00 per year. For sale by all booksellers and newsdealers, or sent post-paid.

By **D. LOTHROP & CO., Publishers,**  
32 Franklin St., Boston, Mass.

**L. E. RANSOM, 34 MAIDEN LANE, N. Y. CITY.**  
L. Perfect Butter Color at lowest prices.

# WINTER & SPRING

**B. K. BLISS & SONS'**  
CHOICE COLLECTIONS.  
**HYACINTHS, CROCUS,**  
**TULIPS, LILIES,**  
**NARCISSUS, &c.**

Our Autumn Catalogue of the above, beautifully illustrated, will be ready for distribution early in September, and will be mailed to all applicants. Customers of last fall will be supplied from our books without application. Address
